Nios II Gen2 Processor Reference Guide

ALTERA

now part of Intel

Contents

We have ended development of new Nios II Classic processor features with the Quartus Prime 14.0 release. New Nios II processor features are implemented only in the Nios II Gen 2 processor core. Although the Classic processor remains supported, we recommend that you use the Gen 2 core for future designs.

This handbook describes the Nios® II Gen2 processor from a high-level conceptual description to the low-level details of implementation. The chapters in this handbook describe the Nios II processor architecture, the programming model, and the instruction set. The Nios II Gen2 processor is only availabe in the Quartus Prime 14.1 release and above.

This handbook assumes you have a basic familiarity with embedded processor concepts. You do not need to be familiar with any specific Altera technology or with Altera development tools. This handbook limits discussion of hardware implementation details of the processor system. The Nios II processors are designed for Altera® FPGA devices, and so this handbook does describe some FPGA implementation concepts. Your familiarity with FPGA technology provides a deeper understanding of the engineering trade-offs related to the design and implementation of the Nios II processor.

This chapter introduces the Altera Nios II embedded processor family and describes the similarities and differences between the Nios II processor and traditional embedded processors.

Related Information

Literature: Nios II Processor

This handbook is the primary reference for the Nios II family of embedded processors and is part of a larger collection of documents covering the Nios II processor and its usage that you can find on the Literature: Nios II Processor Page of the Altera website.

Nios II Processor System Basics

The Nios II processor is a general-purpose RISC processor core with the following features:

- Full 32-bit instruction set, data path, and address space
- 32 general-purpose registers
- Optional shadow register sets
- 32 interrupt sources
- External interrupt controller interface for more interrupt sources
- Single-instruction 32×32 multiply and divide producing a 32-bit result
- Dedicated instructions for computing 64-bit and 128-bit products of multiplication

ALTERA

now part of Intel

- Optional floating-point instructions for single-precision floating-point operations
- Single-instruction barrel shifter
- Access to a variety of on-chip peripherals, and interfaces to off-chip memories and peripherals
- Hardware-assisted debug module enabling processor start, stop, step, and trace under control of the Nios II software development tools
- Optional memory management unit (MMU) to support operating systems that require MMUs
- Optional memory protection unit (MPU)
- Software development environment based on the GNU C/C++ tool chain and the Nios II Software Build Tools (SBT) for Eclipse
- Integration with Altera's SignalTap® II Embedded Logic Analyzer, enabling real-time analysis of instructions and data along with other signals in the FPGA design
- Instruction set architecture (ISA) compatible across all Nios II processor systems
- Performance up to 250 DMIPS
- Error correcting code (ECC) support for all Nios II processor internal RAM blocks

A Nios II processor system is equivalent to a microcontroller or "computer on a chip" that includes a processor and a combination of peripherals and memory on a single chip. A Nios II processor system consists of a Nios II processor core, a set of on-chip peripherals, on-chip memory, and interfaces to off-chip memory, all implemented on a single Altera device. Like a microcontroller family, all Nios II processor systems use a consistent instruction set and programming model.

Getting Started with the Nios II Processor

The easiest way to start designing effectively is to use an Altera development kit that includes a ready-made development board and the Nios II Embedded Design Suite (EDS) containing all the software development tools necessary to write Nios II software.

The Nios II EDS includes the following two closely-related software development tool flows:

- The Nios II SBT
- The Nios II SBT for Eclipse

Both tools flows are based on the GNU C/C++ compiler. The Nios II SBT for Eclipse™ provides a familiar and established environment for software development. Using the Nios II SBT for Eclipse, you can immediately begin developing and simulating Nios II software applications.

The Nios II SBT also provides a command line interface.

Using the Nios II hardware reference designs included in an Altera development kit, you can prototype an application running on a board before building a custom hardware platform.

Figure 1-1: Example of a Nios II Processor System
If the prototype system adequately meets design requirements using an Altera-provided reference design, you can copy the reference design and use it without modification in the final hardware platform. Otherwise, you can customize the Nios II processor system until it meets cost or performance requirements.

For a list of available development kits, refer to the All Development Kits page of the Altera website.

Customizing Nios II Processor Designs

In practice, most FPGA designs implement some extra logic in addition to the processor system. Altera FPGAs provide flexibility to add features and enhance performance of the Nios II processor system. You can also eliminate unnecessary processor features and peripherals to fit the design in a smaller, lower-cost device.

Because the pins and logic resources in Altera devices are programmable, many customizations are possible:

- You can rearrange the pins on the chip to simplify the board design. For example, you can move address and data pins for external SDRAM memory to any side of the chip to shorten board traces.
- You can use extra pins and logic resources on the chip for functions unrelated to the processor. Extra resources can provide a few extra gates and registers as glue logic for the board design; or extra resources can implement entire systems. For example, a Nios II processor system consumes only 5% of a large Altera FPGA, leaving the rest of the chip's resources available to implement other functions.
- You can use extra pins and logic on the chip to implement additional peripherals for the Nios II processor system. Altera offers a library of peripherals that easily connect to Nios II processor systems.

Configurable Soft Processor Core Concepts

This section introduces Nios II concepts that are unique or different from other discrete microcontrollers. The concepts described in this section provide a foundation for understanding the rest of the features discussed in this handbook.

Configurable Soft Processor Core

The Nios II processor is a configurable soft IP core, as opposed to a fixed, off-the-shelf microcontroller. You can add or remove features on a system-by-system basis to meet performance or price goals. Soft means the processor core is not fixed in silicon and can be targeted to any Altera FPGA family.

You are not required to create a new Nios II processor configuration for every new design. Altera provides ready-made Nios II system designs that you can use as is. If these designs meet your system requirements, there is no need to configure the design further. In addition, you can use the Nios II instruction set simulator to begin writing and debugging Nios II applications before the final hardware configuration is determined.

Flexible Peripheral Set and Address Map

A flexible peripheral set is one of the most notable differences between Nios II processor systems and fixed microcontrollers. Because the Nios II processor is implemented in programmable logic, you can easily build made-to-order Nios II processor systems with the exact peripheral set required for the target applications.

Altera provides software constructs to access memory and peripherals generically, independently of address location. Therefore, the flexible peripheral set and address map does not affect application developers.

There are two broad classes of peripherals: standard peripherals and custom peripherals.

Standard Peripherals

Altera provides a set of peripherals commonly used in microcontrollers, such as timers, serial communication interfaces, general-purpose I/O, SDRAM controllers, and other memory interfaces. The list of available peripherals continues to increase as Altera and third-party vendors release new peripherals.

Related Information

Embedded Peripherals IP User Guide
For information about the Altera-provided cores, refer to the Embedded Peripherals IP User Guide.

Custom Components

You can also create custom components and integrate them in Nios II processor systems. For perform-ance-critical systems that spend most CPU cycles executing a specific section of code, it is a common technique to create a custom peripheral that implements the same function in hardware.

This approach offers a double performance benefit:

- Hardware implementation is faster than software.
- Processor is free to perform other functions in parallel while the custom peripheral operates on data.

Related Information

Creating Qsys Components

For information about creating custom components in Qsys, refer to the *Creating Qsys Components* chapter in the *Quartus Prime Handbook, Volume 1*.

Custom Instructions

Like custom peripherals, custom instructions allow you to increase system performance by augmenting the processor with custom hardware. You can achieve significant performance improvements, often on the order of 10 to 100 times, by implementing performance-critical operations in hardware using custom instruction logic.

The custom logic is integrated into the Nios II processor's arithmetic logic unit (ALU). Similar to native Nios II instructions, custom instruction logic can take values from up to two source registers and optionally write back a result to a destination register.

Because the processor is implemented on reprogrammable Altera FPGAs, software and hardware engineers can work together to iteratively optimize the hardware and test the results of software running on hardware.

From the software perspective, custom instructions appear as machine-generated assembly macros or C functions, so programmers do not need to understand assembly language to use custom instructions.

Automated System Generation

Altera's Qsys system integration tools fully automate the process of configuring processor features and generating a hardware design that you program in an Altera device. The Qsys graphical user interface (GUI) enables you to configure Nios II processor systems with any number of peripherals and memory interfaces. You can create entire processor systems without performing any schematic or HDL design entry. Qsys can also import HDL design files, providing an easy mechanism to integrate custom logic in a Nios II processor system.

After system generation, you can download the design onto a board, and debug software executing on the board. To the software developer, the processor architecture of the design is set. Software development proceeds in the same manner as for traditional, nonconfigurable processors.

OpenCore Plus Evaluation

You can evaluate the Nios II processor without a license. With Altera's free OpenCore Plus evaluation feature, you can perform the following actions:

- Simulate the behavior of a Nios II processor within your system.
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily.
- Generate time-limited device programming files for designs that include Nios II processors.
- Program a device and verify your design in hardware.

You only need to purchase a license for the Nios II processor when you are completely satisfied with its functionality and performance, and want to take your design to production.

Document Revision History

Table 1-1: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
April 2015	2015.04.02	Initial release

This chapter describes the hardware structure of the Nios II processor, including a discussion of all the functional units of the Nios II architecture and the fundamentals of the Nios II processor hardware implementation.

The Nios II architecture describes an instruction set architecture (ISA). The ISA in turn necessitates a set of functional units that implement the instructions. A Nios II processor core is a hardware design that implements the Nios II instruction set and supports the functional units described in this document. The processor core does not include peripherals or the connection logic to the outside world. It includes only the circuits required to implement the Nios II architecture.

The Nios II architecture defines the following functional units:

- Register file
- Arithmetic logic unit (ALU)
- Interface to custom instruction logic
- Exception controller
- Internal or external interrupt controller
- Instruction bus
- Data bus
- Memory management unit (MMU)
- Memory protection unit (MPU)
- Instruction and data cache memories
- Tightly-coupled memory interfaces for instructions and data
- JTAG debug module

Figure 2-1: Nios II Processor Core Block Diagram
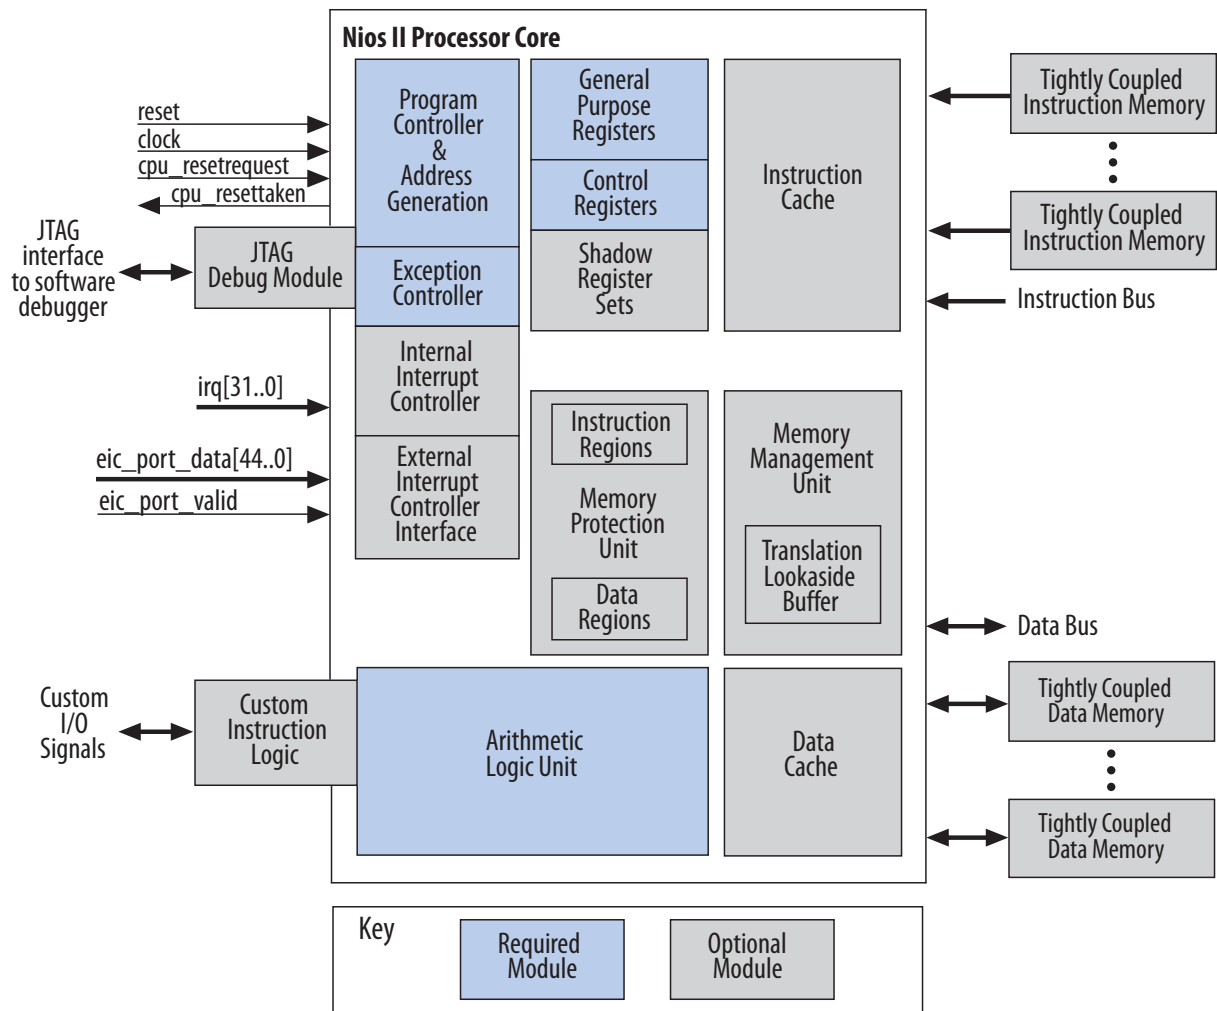

Processor Implementation

The functional units of the Nios II architecture form the foundation for the Nios II instruction set. However, this does not indicate that any unit is implemented in hardware. The Nios II architecture describes an instruction set, not a particular hardware implementation. A functional unit can be implemented in hardware, emulated in software, or omitted entirely.

A Nios II implementation is a set of design choices embodied by a particular Nios II processor core. All implementations support the instruction set defined in the *Instruction Set Reference* chapter.

Each implementation achieves specific objectives, such as smaller core size or higher performance. This flexibility allows the Nios II architecture to adapt to different target applications.

Implementation variables generally fit one of three trade-off patterns: more or less of a feature; inclusion or exclusion of a feature; hardware implementation or software emulation of a feature. An example of each trade-off follows:

- More or less of a feature—For example, to fine-tune performance, you can increase or decrease the amount of instruction cache memory. A larger cache increases execution speed of large programs, while a smaller cache conserves on-chip memory resources.
- Inclusion or exclusion of a feature—For example, to reduce cost, you can choose to omit the JTAG debug module. This decision conserves on-chip logic and memory resources, but it eliminates the ability to use a software debugger to debug applications.
- Hardware implementation or software emulation—For example, in control applications that rarely perform complex arithmetic, you can choose for the division instruction to be emulated in software. Removing the divide hardware conserves on-chip resources but increases the execution time of division operations.

For information about which Nios II cores supports what features, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook.*

For complete details about user-selectable parameters for the Nios II processor, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

Register File

The Nios II architecture supports a flat register file, consisting of thirty-two 32-bit general-purpose integer registers, and up to thirty-two 32-bit control registers. The architecture supports supervisor and user modes that allow system code to protect the control registers from errant applications.

The Nios II processor can optionally have one or more shadow register sets. A shadow register set is a complete set of Nios II general-purpose registers. When shadow register sets are implemented, the `CRS` field of the `status` register indicates which register set is currently in use. An instruction access to a general-purpose register uses whichever register set is active.

A typical use of shadow register sets is to accelerate context switching. When shadow register sets are implemented, the Nios II processor has two special instructions, `rdprs` and `wrprs`, for moving data between register sets. Shadow register sets are typically manipulated by an operating system kernel, and are transparent to application code. A Nios II processor can have up to 63 shadow register sets.

The Nios II architecture allows for the future addition of floating-point registers.

For details about shadow register set implementation and usage, refer to "Registers" and "Exception Processing" in the *Programming Model* chapter of the Nios II Processor Reference Handbook.

For details about the `rdprs` and `wrprs` instructions, refer to the *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook.*

Arithmetic Logic Unit

The Nios II ALU operates on data stored in general-purpose registers. ALU operations take one or two inputs from registers, and store a result back in a register. The ALU supports the data operations described in the table below. To implement any other operation, software computes the result by performing a combination of the fundamental operations.

Table 2-1: Operations Supported by the Nios II ALU

Category	Details
Arithmetic	The ALU supports addition, subtraction, multiplication, and division on signed and unsigned operands.
Relational	The ALU supports the equal, not-equal, greater-than-or-equal, and less-than relational operations (==, != >=, <) on signed and unsigned operands.
Logical	The ALU supports AND, OR, NOR, and XOR logical operations.
Shift and Rotate	The ALU supports shift and rotate operations, and can shift/rotate data by 0 to 31 bit positions per instruction. The ALU supports arithmetic shift right and logical shift right/left. The ALU supports rotate left/right.

Unimplemented Instructions

Some Nios II processor core implementations do not provide hardware to support the entire Nios II instruction set. In such a core, instructions without hardware support are known as unimplemented instructions.

The processor generates an exception whenever it issues an unimplemented instruction so your exception handler can call a routine that emulates the operation in software. Unimplemented instructions do not affect the programmer's view of the processor.

For a list of potential unimplemented instructions, refer to the *Programming Model* chapter of the Nios II Processor Reference Handbook.

Related Information

Programming Model on page 3-1

Custom Instructions

The Nios II architecture supports user-defined custom instructions. The Nios II ALU connects directly to custom instruction logic, enabling you to implement operations in hardware that are accessed and used exactly like native instructions.

Refer to "Custom Instruction Tab" in the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook* for additional information.

Floating-Point Instructions

The Nios II architecture supports single precision floating-point instructions with two components:

- Floating Point Hardware 2—This component supports floating-point instructions as specified by the IEEE Std 754-2008 but with simplified, non-standard rounding modes. The basic set of floating-point custom instructions includes single precision floating-point addition, subtraction, multiplication, division, square root, integer to float conversion, float to integer conversion, minimum, maximum, negate, absolute, and comparisons.
- Floating Point Hardware—This component supports floating-point instructions as specified by the IEEE Std 754-1985. The basic set of floating-point custom instructions includes single precision floating-point addition, subtraction, and multiplication. Floating-point division is available as an extension to the basic instruction set.

These floating-point instructions are implemented as custom instructions. The Hardware Conformance table below lists a detailed description of the conformance to the IEEE standards.

Table 2-2: Hardware Conformance with IEEE 754-1985 and IEEE 754-2008 Floating-Point Standard

Feature		Floating-Point Hardware Implementation with IEEE 754-1985	Floating-Point Hardware 2 Implementation with IEEE 754-2008
Operations	Addition/subtraction	Implemented	Implemented
	Multiplication	Implemented	Implemented
	Division	Optional	Implemented
	Square root	Not implemented, this operation is implemented in software.	Implemented
	Integer to float/float to integer	Not implemented, this operation is implemented in software.	Implemented
	Minimum/maximum	Not implemented, this operation is implemented in software.	Implemented
	Negate/absolute	Not implemented, this operation is implemented in software.	Implemented
	Comparisons	Not implemented, this operation is implemented in software.	Implemented
Precision	Single	Implemented	Implemented
	Double	Not implemented. Double precision operations are implemented in software.	Not implemented. Double precision operations are implemented in software.

Feature		Floating-Point Hardware Implementation with IEEE 754-1985	Floating-Point Hardware 2 Implementation with IEEE 754-2008
Exception conditions	Invalid operation	Result is Not a Number (NaN)	Result is Not a Number (NaN)
	Division by zero	Result is ±infinity	Result is ±infinity
	Overflow	Result is ±infinity	Result is ±infinity
	Inexact	Result is a normal number	Result is a normal number
	Underflow	Result is ±0	Result is ±0
Rounding Modes	Round to nearest	Implemented	Implemented (roundTiesTo-Away mode)
	Round toward zero	Not implemented	Implemented (truncation mode)
	Round toward +infinity	Not implemented	Not implemented
	Round toward −infinity	Not implemented	Not implemented
NaN	Quiet	Implemented	No distinction is made between signaling and quiet NaNs as input operands. A result that produces a NaN may produce either a signaling or quiet NaN.
	Signaling	Not implemented	
Subnormal (denormalized) numbers		Subnormal operands are treated as zero. The floating-point custom instructions do not generate subnormal numbers.	• The comparison, minimum, maximum, negate, and absolute operations support subnormal numbers. • The add, subtract, multiply, divide, square root, and float to integer operations do NOT support subnormal numbers. Subnormal operands are treated as signed zero. The floating-point custom instructions do not generate subnormal numbers.[1] • The integer to float operation cannot create subnormal numbers.

---

[1] This operation is not fully compliant with IEEE 754-2008.

Feature	Floating-Point Hardware Implementation with IEEE 754-1985	Floating-Point Hardware 2 Implementation with IEEE 754-2008
Software exceptions		Not implemented. IEEE 754-1985 exception conditions are detected and handled as described elsewhere in this table.	Not implemented. IEEE 754-2008 exception conditions are detected and handled as described elsewhere in this table.[1]
Status flags		Not implemented. IEEE 754-1985 exception conditions are detected and handled as described elsewhere in this table.	Not implemented. IEEE 754-2008 exception conditions are detected and handled as described elsewhere in this table.[1]

Note: The Floating Point Hardware 2 component also supports faithful rounding, which is not an IEEE 754-defined rounding mode. Faithful rounding rounds results to either the upper or lower nearest single-precision numbers. Therefore, the result produced is one of two possible values and the choice between the two is not defined. The maximum error of faithful rounding is 1 unit in the last place (ulp). Errors may not be evenly distributed.

Nios II Custom Instruction User Guide

For more information about using floating-point custom instructions in software, refer to the *Nios II Custom Instruction User Guide*.

Floating Point Custom Instruction 2 Component

You can add floating-point custom instructions to any Nios II processor design. The floating-point division hardware requires more resources than the other instructions. The Floating Point Hardware 2 component supports the following single-precision floating-point operations:

- Add
- Subtract
- Multiply
- Divide
- Square root
- Comparison
- Integer conversion
- Minimum
- Maximum
- Negate
- Absolute

Other floating-point operations (including double-precision operations) are implemented with software emulation. The component requires the following device resources:

- ~2,500 4-input LEs
- 9 x 9 bit multipliers
- 3x M9K memories

In the following table, a and b are assumed to be single-precision floating-point values.

Table 2-3: Floating Point Custom Instruction 2 Operation Summary

Operation[2]	N[3]	Cycles	Result	Subnormal	Rounding	GCC Inference
fdivs	255	16	$a \div b$	Flush to 0	Nearest	a / b
fsubs	254	5	$a - b$	Flush to 0	Faithful	a – b

fcmpgts	229	1	(a > b) ? 1 : 0	Supported	None	a > b
fcmpges	228	1	(a ≥ b) ? 1 : 0	Supported	None	a >= b
fcmpeqs	227	1	(a = b) ? 1 : 0	Supported	None	a == b
fcmpnes	226	1	(a ≠ b) ? 1 : 0	Supported	None	a != b
fnegs	225	1	-a	Supported	None	-a
fabss	224	1	|a|	Supported	None	fabsf()

The cycles column specifies the number of cycles required to execute the instruction. A combinatorial custom instruction takes 1 cycle. A multi-cycle custom instruction requires at least 2 cycles. An N-cycle multi-cycle custom instruction has N - 2 register stages inside the custom instruction because the Nios II processor registers the result from the custom instruction and allows another cycle for g wire delays in the source operand bypass multiplexers. The number of cycles does not include the extra cycles (maximum of 2) that an instruction following the multi-cycle custom instruction is stalled by the Nios II/f if the instruc-

---

[2] These names match the names of the corresponding GCC command-line options except for round, which GCC does not support.

[3] Specifies the 8 bit fixed custom instruction for the operation.

[4] Nios II GCC version 4.7.3 is not able to reliably replace calls to newlib floating-point functions with the equivalent custom instruction even though it has `-mcustom-<operation>` command-line options and pragma support for these operations. Instead, the custom instruction must be invoked directly using the GCC `__builtin_custom_*` facility. The Floating Point Custom Instruction 2 component includes a C header file that provides the required `#define` macros to invoke the custom instruction directly.

tion uses the result within 2 cycles. These extra cycles occur because multi-cycle instructions are late result instructions

In Qsys, the **Floating Point Hardware 2** component is under **Embedded Processors** on the **Component Library** tab.

The Nios II Software Build Tools (SBT) include software support for the Floating Point Custom Instruction 2 component. When the Floating Point Custom Instruction 2 component is present in hardware, the Nios II compiler compiles the software codes to use the custom instructions for floating point operations.

Floating Point Custom Instruction Component

The Floating Point Hardware component supports addition, subtraction, multiplication, and (optionally) division. The Floating Point Hardware parameter editor allows you to omit the floating-point division hardware for cases in which code running on your hardware design does not make heavy use of floating-point division. When you omit the floating-point divide instruction, the Nios II compiler implements floating-point division in software.

In Qsys, the **Floating Point Hardware** component is under **Embedded Processors** on the **Component Library** tab.

The Nios II floating-point custom instructions are based on the Altera$^®$ floating-point megafunctions: ALTFP_MULT, ALTFP_ADD_SUB, and ALTFP_DIV.

The Nios II software development tools recognize C code that takes advantage of the floating-point instructions present in the processor core. When the floating-point custom instructions are present in your target hardware, the Nios II compiler compiles your code to use the custom instructions for floating-point operations and the newlib math library.

IP and Megafunctions
For information about each individual floating-point megafunction, including acceleration factors and device resource usage, refer to the megafunction user guides, available on the IP and Megafunctions literature page of the Altera website.

Reset and Debug Signals

The table below describes the reset and debug signals that the Nios II processor core supports.

Table 2-4: Nios II Processor Debug and Reset Signals

Signal Name	Type	Purpose
reset	Reset	This is a global hardware reset signal that forces the processor core to reset immediately.

Signal Name	Type	Purpose
cpu_resetrequest	Reset	This is an optional, local reset signal that causes the processor to reset without affecting other components in the Nios II system. The processor finishes executing any instructions in the pipeline, and then enters the reset state. This process can take several clock cycles, so be sure to continue asserting the cpu_resetrequest signal until the processor core asserts a cpu_resettaken signal.

The processor core asserts a cpu_resettaken signal for 1 cycle when the reset is complete and then periodically if cpu_resetrequest remains asserted. The processor remains in the reset state for as long as cpu_resetrequest is asserted. While the processor is in the reset state, it periodically reads from the reset address. It discards the result of the read, and remains in the reset state.

The processor does not respond to cpu_resetrequest when the processor is under the control of the JTAG debug module, that is, when the processor is paused. The processor responds to the cpu_resetrequest signal if the signal is asserted when the JTAG debug module relinquishes control, both momentarily during each single step as well as when you resume execution. |
| debugreq | Debug | This is an optional signal that temporarily suspends the processor for debugging purposes. When you assert the signal, the processor pauses in the same manner as when a breakpoint is encountered, transfers execution to the routine located at the break address, and asserts a debugack signal. Asserting the debugreq signal when the processor is already paused has no effect. |
| reset_req | Reset | This optional signal prevents the memory corruption by performing a reset handshake before the processor resets. |

For more information on adding reset signals to the Nios II processor, refer to "Advanced Features Tab" in the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

For more information on the break vector and adding debug signals to the Nios II processor, refer to "JTAG Debug Module Tab" in the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

Instantiating the Nios II Gen2 Processor on page 4-1

Exception and Interrupt Controllers

The Nios II processor includes hardware for handling exceptions, including hardware interrupts. It also includes an optional external interrupt controller (EIC) interface. The EIC interface enables you to speed up interrupt handling in a complex system by adding a custom interrupt controller.

Exception Controller

The Nios II architecture provides a simple, nonvectored exception controller to handle all exception types. Each exception, including internal hardware interrupts, causes the processor to transfer execution to an

exception address. An exception handler at this address determines the cause of the exception and dispatches an appropriate exception routine.

Exception addresses are specified with the Qsys Nios II Processor parameter editor.

All exceptions are precise. Precise means that the processor has completed execution of all instructions preceding the faulting instruction and not started execution of instructions following the faulting instruction. Precise exceptions allow the processor to resume program execution once the exception handler clears the exception.

EIC Interface

An EIC provides high performance hardware interrupts to reduce your program's interrupt latency. An EIC is typically used in conjunction with shadow register sets and when you need more than the 32 interrupts provided by the Nios II internal interrupt controller.

The Nios II processor connects to an EIC through the EIC interface. When an EIC is present, the internal interrupt controller is not implemented; Qsys connects interrupts to the EIC.

The EIC selects among active interrupts and presents one interrupt to the Nios II processor, with interrupt handler address and register set selection information. The interrupt selection algorithm is specific to the EIC implementation, and is typically based on interrupt priorities. The Nios II processor does not depend on any specific interrupt prioritization scheme in the EIC.

For every external interrupt, the EIC presents an interrupt level. The Nios II processor uses the interrupt level in determining when to service the interrupt.

Any external interrupt can be configured as an NMI. NMIs are not masked by the `status.PIE` bit, and have no interrupt level.

An EIC can be software-configurable.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or higher. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

For a typical example of an EIC, refer to the *Vectored Interrupt Controller* chapter in the Embedded Peripherals IP User Guide.

For details about EIC usage, refer to "Exception Processing" in the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

- **Embedded Peripherals IP User Guide**
  For a typical example of an EIC, refer to the *Vectored Interrupt Controller* chapter in the *Embedded Peripherals IP User Guide*.

Internal Interrupt Controller

The Nios II architecture supports 32 internal hardware interrupts. The processor core has 32 level-sensitive interrupt request (IRQ) inputs, `irq0` through `irq31`, providing a unique input for each interrupt source. IRQ priority is determined by software. The architecture supports nested interrupts.

Your software can enable and disable any interrupt source individually through the `ienable` control register, which contains an interrupt-enable bit for each of the IRQ inputs. Software can enable and disable

Send Feedback

interrupts globally using the PIE bit of the `status` control register. A hardware interrupt is generated if and only if all of the following conditions are true:

- The PIE bit of the `status` register is 1
- An interrupt-request input, `irq<n>`, is asserted
- The corresponding bit n of the `ienable` register is 1

The interrupt vector custom instruction is less efficient than using the EIC interface with the Altera vectored interrupt controller component, and thus is deprecated in Qsys. Altera recommends using the EIC interface.

Memory and I/O Organization

This section explains hardware implementation details of the Nios II memory and I/O organization. The discussion covers both general concepts true of all Nios II processor systems, as well as features that might change from system to system.

The flexible nature of the Nios II memory and I/O organization are the most notable difference between Nios II processor systems and traditional microcontrollers. Because Nios II processor systems are configurable, the memories and peripherals vary from system to system. As a result, the memory and I/O organization varies from system to system.

A Nios II core uses one or more of the following to provide memory and I/O access:

- Instruction master port—An Avalon® Memory-Mapped (Avalon-MM) master port that connects to instruction memory via system interconnect fabric
- Instruction cache—Fast cache memory internal to the Nios II core
- Data master port—An Avalon-MM master port that connects to data memory and peripherals via system interconnect fabric
- Data cache—Fast cache memory internal to the Nios II core
- Tightly-coupled instruction or data memory port—Interface to fast on-chip memory outside the Nios II core

The Nios II architecture handles the hardware details for the programmer, so programmers can develop Nios II applications without specific knowledge of the hardware implementation.

For details that affect programming issues, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Programming Model on page 3-1

Instruction and Data Buses

The Nios II architecture supports separate instruction and data buses, classifying it as a Harvard architecture. Both the instruction and data buses are implemented as Avalon-MM master ports that adhere to the Avalon-MM interface specification. The data master port connects to both memory and peripheral components, while the instruction master port connects only to memory components.

Note: The Nios II instruction and data masters have a combined address map. The memory model is arranged so that instructions and data are in the same address space.

Send Feedback

Related Information
Avalon Interface Specifications
Refer to the Avalon Interface Specifications for details of the Avalon-MM interface.

Memory and Peripheral Access

The Nios II architecture provides memory-mapped I/O access. Both data memory and peripherals are mapped into the address space of the data master port. The Nios II architecture uses little-endian byte ordering. Words and halfwords are stored in memory with the more-significant bytes at higher addresses.

The Nios II architecture does not specify anything about the existence of memory and peripherals; the quantity, type, and connection of memory and peripherals are system-dependent. Typically, Nios II processor systems contain a mix of fast on-chip memory and slower off-chip memory. Peripherals typically reside on-chip, although interfaces to off-chip peripherals also exist.

Instruction Master Port

The Nios II instruction bus is implemented as a 32-bit Avalon-MM master port. The instruction master port performs a single function: it fetches instructions to be executed by the processor. The instruction master port does not perform any write operations.

The instruction master port is a pipelined Avalon-MM master port. Support for pipelined Avalon-MM transfers minimizes the impact of synchronous memory with pipeline latency and increases the overall f_{MAX} of the system. The instruction master port can issue successive read requests before data has returned from prior requests. The Nios II processor can prefetch sequential instructions and perform branch prediction to keep the instruction pipe as active as possible.

The instruction master port always retrieves 32 bits of data. The instruction master port relies on dynamic bus-sizing logic contained in the system interconnect fabric. By virtue of dynamic bus sizing, every instruction fetch returns a full instruction word, regardless of the width of the target memory. Consequently, programs do not need to be aware of the widths of memory in the Nios II processor system.

The Nios II architecture supports on-chip cache memory for improving average instruction fetch performance when accessing slower memory. Refer to the "Cache Memory" section of this chapter for details.

The Nios II architecture supports tightly-coupled memory, which provides guaranteed low-latency access to on-chip memory. Refer to the "Tightly-Coupled Memory" section of this chapter for details.

Related Information

- **Cache Memory** on page 2-15
- **Tightly-Coupled Memory** on page 2-16

Data Master Port

The Nios II data bus is implemented as a 32-bit Avalon-MM master port. The data master port performs two functions:

- Read data from memory or a peripheral when the processor executes a load instruction
- Write data to memory or a peripheral when the processor executes a store instruction

Byte-enable signals on the master port specify which of the four byte-lane(s) to write during store operations. Load and store operations can complete in a single clock cycle when the data master port is connected to zero-wait-state memory.

Note: Nios II Gen2 only supports a fixed 32-byte linesize for data cache.

The Nios II architecture supports on-chip cache memory for improving average data transfer performance when accessing slower memory. Refer to the "Cache Memory" section of this chapter for details.

The Nios II architecture supports tightly-coupled memory, which provides guaranteed low-latency access to on-chip memory. Refer to "Tightly-Coupled Memory" section of this chapter for details.

Related Information

- **Cache Memory** on page 2-15
- **Tightly-Coupled Memory** on page 2-16

Shared Memory for Instructions and Data

Usually the instruction and data master ports share a single memory that contains both instructions and data. While the processor core has separate instruction and data buses, the overall Nios II processor system might present a single, shared instruction/data bus to the outside world. The outside view of the Nios II processor system depends on the memory and peripherals in the system and the structure of the system interconnect fabric.

The data and instruction master ports never cause a gridlock condition in which one port starves the other. For highest performance, assign the data master port higher arbitration priority on any memory that is shared by both instruction and data master ports.

Cache Memory

The Nios II architecture supports cache memories on both the instruction master port (instruction cache) and the data master port (data cache). Cache memory resides on-chip as an integral part of the Nios II processor core. The cache memories can improve the average memory access time for Nios II processor systems that use slow off-chip memory such as SDRAM for program and data storage.

The instruction and data caches are enabled perpetually at run-time, but methods are provided for software to bypass the data cache so that peripheral accesses do not return cached data. Cache management and cache coherency are handled by software. The Nios II instruction set provides instructions for cache management.

Configurable Cache Memory Options

The cache memories are optional. The need for higher memory performance (and by association, the need for cache memory) is application dependent. Many applications require the smallest possible processor core, and can trade-off performance for size.

A Nios II processor core might include one, both, or neither of the cache memories. Furthermore, for cores that provide data and/or instruction cache, the sizes of the cache memories are user-configurable. The inclusion of cache memory does not affect the functionality of programs, but it does affect the speed at which the processor fetches instructions and reads/writes data.

Effective Use of Cache Memory

The effectiveness of cache memory to improve performance is based on the following premises:

- Regular memory is located off-chip, and access time is long compared to on-chip memory
- The largest, performance-critical instruction loop is smaller than the instruction cache
- The largest block of performance-critical data is smaller than the data cache

Optimal cache configuration is application specific, although you can make decisions that are effective across a range of applications. For example, if a Nios II processor system includes only fast, on-chip memory (i.e., it never accesses slow, off-chip memory), an instruction or data cache is unlikely to offer any performance gain. As another example, if the critical loop of a program is 2 KB, but the size of the instruction cache is 1 KB, an instruction cache does not improve execution speed. In fact, an instruction cache may degrade performance in this situation.

If an application always requires certain data or sections of code to be located in cache memory for performance reasons, the tightly-coupled memory feature might provide a more appropriate solution. Refer to the "Tightly-Coupled Memory" section for details.

Cache Bypass Methods

The Nios II architecture provides the following methods for bypassing the data cache:

- I/O load and store instructions
- Bit-31 cache bypass
- Peripheral Region

Note: By default the Bit-31 cache bypass is turned on.

I/O Load and Store Instructions Method

The load and store I/O instructions such as `ldio` and `stio` bypass the data cache and force an Avalon-MM data transfer to a specified address.

The Bit-31 Cache Bypass Method

The bit-31 cache bypass method on the data master port uses bit 31 of the address as a tag that indicates whether the processor should transfer data to/from cache, or bypass it. This is a convenience for software, which might need to cache certain addresses and bypass others. Software can pass addresses as parameters between functions, without having to specify any further information about whether the addressed data is cached or not.

To determine which cores implement which cache bypass methods, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Nios II Core Implementation Details on page 5-1

Peripheral Region

Gen2 cores optionally support a new peripheral region mechanism to indicate cacheability. The peripheral region cacheability mechanism allows a user at Qsys generation time to specify a region of address space that is treated as non-cacheable. The peripheral region is any integer power of 2 bytes from a minimum of 4096 bytes up to a maximum of 2 GBytes and must be located at a base address aligned to the size of the peripheral region. The peripheral region is available as long as an MMU is not present.

Tightly-Coupled Memory

Tightly-coupled memory provides guaranteed low-latency memory access for performance-critical applications. Compared to cache memory, tightly-coupled memory provides the following benefits:

- Performance similar to cache memory
- Software can guarantee that performance-critical code or data is located in tightly-coupled memory
- No real-time caching overhead, such as loading, invalidating, or flushing memory

Physically, a tightly-coupled memory port is a separate master port on the Nios II processor core, similar to the instruction or data master port. A Nios II core can have zero, one, or multiple tightly-coupled memories. The Nios II architecture supports tightly-coupled memory for both instruction and data access. Each tightly-coupled memory port connects directly to exactly one memory with guaranteed low, fixed latency. The memory is external to the Nios II core and is located on chip.

Accessing Tightly-Coupled Memory

Tightly-coupled memories occupy normal address space, the same as other memory devices connected via system interconnect fabric. The address ranges for tightly-coupled memories (if any) are determined at system generation time.

Software accesses tightly-coupled memory using regular load and store instructions. From the software's perspective, there is no difference accessing tightly-coupled memory compared to other memory.

Effective Use of Tightly-Coupled Memory

A system can use tightly-coupled memory to achieve maximum performance for accessing a specific section of code or data. For example, interrupt-intensive applications can place exception handler code into a tightly-coupled memory to minimize interrupt latency. Similarly, compute-intensive digital signal processing (DSP) applications can place data buffers into tightly-coupled memory for the fastest possible data access.

If the application's memory requirements are small enough to fit entirely on chip, it is possible to use tightly-coupled memory exclusively for code and data. Larger applications must selectively choose what to include in tightly-coupled memory to maximize the cost-performance trade-off.

Related Information

Using Tightly Coupled Memory with the Nios II Processor Tutorial

For additional tightly-coupled memory guidelines, refer to the *Using Tightly Coupled Memory with the Nios II Processor tutorial.*

Address Map

The address map for memories and peripherals in a Nios II processor system is design dependent. You specify the address map in Qsys.

There are three addresses that are part of the processor and deserve special mention:

- Reset address
- Exception address
- Break handler address

Programmers access memories and peripherals by using macros and drivers. Therefore, the flexible address map does not affect application developers.

Memory Management Unit

The optional Nios II MMU provides the following features and functionality:

- Virtual to physical address mapping
- Memory protection
- 32-bit virtual and physical addresses, mapping a 4-GB virtual address space into as much as 4 GB of physical memory
- 4-KB page and frame size
- Low 512 MB of physical address space available for direct access

- Hardware translation lookaside buffers (TLBs), accelerating address translation

  - Separate TLBs for instruction and data accesses
  - Read, write, and execute permissions controlled per page
  - Default caching behavior controlled per page
  - TLBs acting as n-way set-associative caches for software page tables
  - TLB sizes and associativities configurable in the Nios II Processor parameter editor
- Format of page tables (or equivalent data structures) determined by system software
- Replacement policy for TLB entries determined by system software
- Write policy for TLB entries determined by system software

For more information about the MMU implementation, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook.*

You can optionally include the MMU when you instantiate the Nios II processor in your Nios II hardware system. When present, the MMU is always enabled, and the data and instruction caches are virtually-indexed, physically-tagged caches. Several parameters are available, allowing you to optimize the MMU for your system needs.

For complete details about user-selectable parameters for the Nios II MMU, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

Note: The Nios II MMU is optional and mutually exclusive from the Nios II MPU. Nios II systems can include either an MMU or MPU, but cannot include both an MMU and MPU on the same Nios II processor core.

Related Information

- **Programming Model** on page 3-1
- **Instantiating the Nios II Gen2 Processor** on page 4-1

Memory Protection Unit

The optional Nios II MPU provides the following features and functionality:

- Memory protection
- Up to 32 instruction regions and 32 data regions
- Variable instruction and data region sizes
- Amount of region memory defined by size or upper address limit
- Read and write access permissions for data regions
- Execute access permissions for instruction regions
- Overlapping regions

For more information about the MPU implementation, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook.*

You can optionally include the MPU when you instantiate the Nios II processor in your Nios II hardware system. When present, the MPU is always enabled. Several parameters are available, allowing you to optimize the MPU for your system needs.

For complete details about user-selectable parameters for the Nios II MPU, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

Note: The Nios II MPU is optional and mutually exclusive from the Nios II MMU. Nios II systems can include either an MPU or MMU, but cannot include both an MPU and MMU on the same Nios II processor core.

JTAG Debug Module

The Nios II architecture supports a JTAG debug module that provides on-chip emulation features to control the processor remotely from a host PC. PC-based software debugging tools communicate with the JTAG debug module and provide facilities, such as the following features:

- Downloading programs to memory
- Starting and stopping execution
- Setting breakpoints and watchpoints
- Analyzing registers and memory
- Collecting real-time execution trace data

Note: The Nios II MMU does not support the JTAG debug module trace.

The debug module connects to the JTAG circuitry in an Altera FPGA. External debugging probes can then access the processor via the standard JTAG interface on the FPGA. On the processor side, the debug module connects to signals inside the processor core. The debug module has nonmaskable control over the processor, and does not require a software stub linked into the application under test. All system resources visible to the processor in supervisor mode are available to the debug module. For trace data collection, the debug module stores trace data in memory either on-chip or in the debug probe.

The debug module gains control of the processor either by asserting a hardware break signal, or by writing a break instruction into program memory to be executed. In both cases, the processor transfers execution to the routine located at the break address. The break address is specified with the Nios II Processor parameter editor in Qsys.

Soft processor cores such as the Nios II processor offer unique debug capabilities beyond the features of traditional, fixed processors. The soft nature of the Nios II processor allows you to debug a system in development using a full-featured debug core, and later remove the debug features to conserve logic resources. For the release version of a product, the JTAG debug module functionality can be reduced, or removed altogether.

The following sections describe the capabilities of the Nios II JTAG debug module hardware. The usage of all hardware features is dependent on host software, such as the Nios II Software Build Tools for Eclipse, which manages the connection to the target processor and controls the debug process.

JTAG Target Connection

The JTAG target connection provides the ability to connect to the processor through the standard JTAG pins on the Altera FPGA. This provides basic capabilities to start and stop the processor, and examine and edit registers and memory. The JTAG target connection is the minimum requirement for the Nios II flash programmer.

Note: While the processor has no minimum clock frequency requirements, Altera recommends that your design's system clock frequency be at least four times the JTAG clock frequency to ensure that the on-chip instrumentation (OCI) core functions properly.

Download and Execute Software

Downloading software refers to the ability to download executable code and data to the processor's memory via the JTAG connection. After downloading software to memory, the JTAG debug module can then exit debug mode and transfer execution to the start of executable code.

Software Breakpoints

Software breakpoints allow you to set a breakpoint on instructions residing in RAM. The software breakpoint mechanism writes a break instruction into executable code stored in RAM. When the processor executes the break instruction, control is transferred to the JTAG debug module.

Hardware Breakpoints

Hardware breakpoints allow you to set a breakpoint on instructions residing in nonvolatile memory, such as flash memory. The hardware breakpoint mechanism continuously monitors the processor's current instruction address. If the instruction address matches the hardware breakpoint address, the JTAG debug module takes control of the processor.

Hardware breakpoints are implemented using the JTAG debug module's hardware trigger feature.

Hardware Triggers

Hardware triggers activate a debug action based on conditions on the instruction or data bus during real-time program execution. Triggers can do more than halt processor execution. For example, a trigger can be used to enable trace data collection during real-time processor execution.

Hardware trigger conditions are based on either the instruction or data bus. Trigger conditions on the same bus can be logically ANDed, enabling the JTAG debug module to trigger, for example, only on write cycles to a specific address.

Table 2-5: Trigger Conditions

Condition	Bus	Description
Specific address	Data, Instruction	Trigger when the bus accesses a specific address.
Specific data value	Data	Trigger when a specific data value appears on the bus.
Read cycle	Data	Trigger on a read bus cycle.
Write cycle	Data	Trigger on a write bus cycle.
Armed	Data, Instruction	Trigger only after an armed trigger event. Refer to the Armed Triggers section.
Range	Data	Trigger on a range of address values, data values, or both. Refer to the Triggering on Ranges of Values section.

When a trigger condition occurs during processor execution, the JTAG debug module triggers an action, such as halting execution, or starting trace capture. The table below lists the trigger actions supported by the Nios II JTAG debug module.

Table 2-6: Trigger Actions

Action	Description
Break	Halt execution and transfer control to the JTAG debug module.
External trigger	Assert a trigger signal output. This trigger output can be used, for example, to trigger an external logic analyzer.
Trace on	Turn on trace collection.
Trace off	Turn off trace collection.
Trace sample	Store one sample of the bus to trace buffer.
Arm	Enable an armed trigger.

Note: For the *Trace sample* triger action, only conditions on the data bus can trigger this action.

Armed Triggers

The JTAG debug module provides a two-level trigger capability, called armed triggers. Armed triggers enable the JTAG debug module to trigger on event B, only after event A. In this example, event A causes a trigger action that enables the trigger for event B.

Triggering on Ranges of Values

The JTAG debug module can trigger on ranges of data or address values on the data bus. This mechanism uses two hardware triggers together to create a trigger condition that activates on a range of values within a specified range.

Trace Capture

Trace capture refers to ability to record the instruction-by-instruction execution of the processor as it executes code in real-time. The JTAG debug module offers the following trace features:

- Capture execution trace (instruction bus cycles).
- Capture data trace (data bus cycles).
- For each data bus cycle, capture address, data, or both.
- Start and stop capturing trace in real time, based on triggers.
- Manually start and stop trace under host control.
- Optionally stop capturing trace when trace buffer is full, leaving the processor executing.
- Store trace data in on-chip memory buffer in the JTAG debug module. (This memory is accessible only through the JTAG connection.)
- Store trace data to larger buffers in an off-chip debug probe.

Certain trace features require additional licensing or debug tools from third-party debug providers. For example, an on-chip trace buffer is a standard feature of the Nios II processor, but using an off-chip trace buffer requires additional debug software and hardware provided by Imagination Technologies™, LLC or Lauterbach GmbH.

Related Information

Lauterbach.com
For more information, refer to the Lauterbach GmbH website.

Execution vs. Data Trace

The JTAG debug module supports tracing the instruction bus (execution trace), the data bus (data trace), or both simultaneously. Execution trace records only the addresses of the instructions executed, enabling you to analyze where in memory (that is, in which functions) code executed. Data trace records the data associated with each load and store operation on the data bus.

The JTAG debug module can filter the data bus trace in real time to capture the following:

- Load addresses only
- Store addresses only
- Both load and store addresses
- Load data only
- Load address and data
- Store address and data
- Address and data for both loads and stores
- Single sample of the data bus upon trigger event

Trace Frames

A frame is a unit of memory allocated for collecting trace data. However, a frame is not an absolute measure of the trace depth.

To keep pace with the processor executing in real time, execution trace is optimized to store only selected addresses, such as branches, calls, traps, and interrupts. From these addresses, host-side debug software can later reconstruct an exact instruction-by-instruction execution trace. Furthermore, execution trace data is stored in a compressed format, such that one frame represents more than one instruction. As a result of these optimizations, the actual start and stop points for trace collection during execution might vary slightly from the user-specified start and stop points.

Data trace stores 100% of requested loads and stores to the trace buffer in real time. When storing to the trace buffer, data trace frames have lower priority than execution trace frames. Therefore, while data frames are always stored in chronological order, execution and data trace are not guaranteed to be exactly synchronized with each other.

This chapter describes the Nios® II programming model, covering processor features at the assembly language level. Fully understanding the contents of this chapter requires prior knowledge of computer architecture, operating systems, virtual memory and memory management, software processes and process management, exception handling, and instruction sets. This chapter assumes you have a detailed understanding of these concepts and focuses on how these concepts are specifically implemented in the Nios II processor. Where possible, this chapter uses industry-standard terminology.

Note: Because of the flexibility and capability range of the Nios II processor, this chapter covers topics that support a variety of operating systems and runtime environments. While reading, be aware that all sections might not apply to you. For example, if you are using a minimal system runtime environment, you can ignore the sections covering operating modes, the MMU, the MPU, or the control registers exclusively used by the MMU and MPU.

Related Information

Nios II Software Developer's Handbook

High-level software development tools are not discussed here. Refer to the Nios II Software Developer's Handbook for information about developing software.

Operating Modes

Operating modes control how the processor operates, manages system memory, and accesses peripherals. The Nios II architecture supports these operating modes:

- Supervisor mode
- User mode

The following sections define the modes, their relationship to your system software and application code, and their relationship to the Nios II MMU and Nios II MPU.

Supervisor Mode

Supervisor mode allows unrestricted operation of the processor. All code has access to all processor instructions and resources. The processor may perform any operation the Nios II architecture provides. Any instruction may be executed, any I/O operation may be initiated, and any area of memory may be accessed.

Operating systems and other system software run in supervisor mode. In systems with an MMU, application code runs in user mode, and the operating system, running in supervisor mode, controls the applica-

ISO 9001:2008 Registered

ALTERA
now part of Intel

tion's access to memory and peripherals. In systems with an MPU, your system software controls the mode in which your application code runs. In Nios II systems without an MMU or MPU, all application and system code runs in supervisor mode.

Code that needs direct access to and control of the processor runs in supervisor mode. For example, the processor enters supervisor mode whenever a processor exception (including processor reset or break) occurs. Software debugging tools also use supervisor mode to implement features such as breakpoints and watchpoints.

Note: For systems without an MMU or MPU, all code runs in supervisor mode.

User Mode

User mode is available only when the Nios II processor in your hardware design includes an MMU or MPU. User mode exists solely to support operating systems. Operating systems (that make use of the processor's user mode) run your application code in user mode. The user mode capabilities of the processor are a subset of the supervisor mode capabilities. Only a subset of the instruction set is available in user mode.

The operating system determines which memory addresses are accessible to user mode applications. Attempts by user mode applications to access memory locations without user access enabled are not permitted and cause an exception. Code running in user mode uses system calls to make requests to the operating system to perform I/O operations, manage memory, and access other system functionality in the supervisor memory.

The Nios II MMU statically divides the 32-bit virtual address space into user and supervisor partitions. Refer to Address Space and Memory Partitions section for more information about the MMU memory partitions. The MMU provides operating systems access permissions on a per-page basis. Refer to Virtual Addressing for more information about MMU pages.

The Nios II MPU supervisor and user memory divisions are determined by the operating system or runtime environment. The MPU provides user access permissions on a region basis. Refer to Memory Regions for more information about MPU regions.

Related Information

- **Memory Regions** on page 3-8
- **Virtual Addressing** on page 3-3

Memory Management Unit

The Nios II processor provides an MMU to support full-featured operating systems. Operating systems that require virtual memory rely on an MMU to manage the virtual memory. When present, the MMU manages memory accesses including translation of virtual addresses to physical addresses, memory protection, cache control, and software process memory allocation.

Recommended Usage

Including the Nios II MMU in your Nios II hardware system is optional. The MMU is only useful with an operating system that takes advantage of it.

Many Nios II systems have simpler requirements where minimal system software or a small-footprint operating system (such as the Altera® hardware abstraction library (HAL) or a third party real-time operating system) is sufficient. Such software is unlikely to function correctly in a hardware system with an

MMU-based Nios II processor. Do not include an MMU in your Nios II system unless your operating system requires it.

Note: The Altera HAL and HAL-based real-time operating systems do not support the MMU.

If your system needs memory protection, but not virtual memory management, refer to Memory Protection Unit section.

Related Information
Memory Protection Unit on page 3-7

Memory Management

Memory management comprises two key functions:

- Virtual addressing—Mapping a virtual memory space into a physical memory space
- Memory protection—Allowing access only to certain memory under certain conditions

Virtual Addressing

A virtual address is the address that software uses. A physical address is the address which the hardware outputs on the address lines of the Avalon® bus. The Nios II MMU divides virtual memory into 4-KB pages and physical memory into 4-KB frames.

The MMU contains a hardware translation lookaside buffer (TLB). The operating system is responsible for creating and maintaining a page table (or equivalent data structures) in memory. The hardware TLB acts as a software managed cache for the page table. The MMU does not perform any operations on the page table, such as hardware table walks. Therefore the operating system is free to implement its page table in any appropriate manner.

There is a 20 bit virtual page number (VPN) and a 12 bit page offset.

Table 3-1: MMU Virtual Address Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Virtual Page Number															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Virtual Page Number				Page Offset											

As input, the TLB takes a VPN plus a process identifier (to guarantee uniqueness). As output, the TLB provides the corresponding physical frame number (PFN).

Distinct processes can use the same virtual address space. The process identifier, concatenated with the virtual address, distinguishes identical virtual addresses in separate processes. To determine the physical address, the Nios II MMU translates a VPN to a PFN and then concatenates the PFN with the page offset. The bits in the page offset are not translated.

Memory Protection

The Nios II MMU maintains read, write, and execute permissions for each page. The TLB provides the permission information when translating a VPN. The operating system can control whether or not each process is allowed to read data from, write data to, or execute instructions on each particular page. The MMU also controls whether accesses to each data page are cacheable or uncacheable by default.

Whenever an instruction attempts to access a page that either has no TLB mapping, or lacks the appropriate permissions, the MMU generates an exception. The Nios II processor's precise exceptions enable the system software to update the TLB, and then re-execute the instruction if desired.

Memory Protection

The Nios II MMU maintains read, write, and execute permissions for each page. The TLB provides the permission information when translating a VPN. The operating system can control whether or not each process is allowed to read data from, write data to, or execute instructions on each particular page. The MMU also controls whether accesses to each data page are cacheable or uncacheable by default.

Whenever an instruction attempts to access a page that either has no TLB mapping, or lacks the appropriate permissions, the MMU generates an exception. The Nios II processor's precise exceptions enable the system software to update the TLB, and then re-execute the instruction if desired.

Address Space and Memory Partitions

The MMU provides a 4-GB virtual address space, and is capable of addressing up to 4 GB of physical memory.

Note: The amount of actual physical memory, determined by the configuration of your hardware system, might be less than the available 4 GB of physical address space.

Virtual Memory Address Space

The 4-GB virtual memory space is divided into partitions. The upper 2 GB of memory is reserved for the operating system and the lower 2 GB is reserved for user processes.

Table 3-2: Virtual Memory Partitions

Partition	Virtual Address Range	Used By	Memory Access	User Mode Access	Default Data Cacheability
I/O	`0xE0000000–0xFFFFFFFF`	Operating system	Bypasses TLB	No	Disabled
Kernel	`0xC0000000–0xDFFFFFFF`	Operating system	Bypasses TLB	No	Enabled
Kernel MMU	`0x80000000–0xBFFFFFFF`	Operating system	Uses TLB	No	Set by TLB
User	`0x00000000–0x7FFFFFFF`	User processes	Uses TLB	Set by TLB	Set by TLB

Note: All partitions except the user partition in the "Virtual Memory Partition" table are supervisor-only partitions.

Each partition has a specific size, purpose, and relationship to the TLB:

- The 512-MB I/O partition provides access to peripherals.
- The 512-MB kernel partition provides space for the operating system kernel.
- The 1-GB kernel MMU partition is used by the TLB miss handler and kernel processes.
- The 2-GB user partition is used by application processes.

I/O and kernel partitions bypass the TLB. The kernel MMU and user partitions use the TLB. If all software runs in the kernel partition, the MMU is effectively disabled.

Physical Memory Address Space

The 4-GB physical memory is divided into low memory and high memory. The lowest ½ GB of physical address space is low memory. The upper 3½ GB of physical address space is high memory.

Figure 3-1: Division of Physical Memory

```
0xFFFFFFFF

                      3.5 GByte High Memory      Accessed only via TLB

0x20000000
0x1FFFFFFF
                      0.5 GByte Low Memory        Accessed directly or via TLB
0x00000000
```
High physical memory can only be accessed through the TLB. Any physical address in low memory (29-bits or less) can be accessed through the TLB or by bypassing the TLB. When bypassing the TLB, a 29-bit physical address is computed by clearing the top three bits of the 32-bit virtual address.

Note: To function correctly, the base physical address of all exception vectors (reset, general exception, break, and fast TLB miss) must point to low physical memory so that hardware can correctly map their virtual addresses into the kernel partition. The Nios II Processor parameter editor in Qsys prevents you from choosing an address outside of low physical memory.

Data Cacheability

Each partition has a rule that determines the default data cacheability property of each memory access. When data cacheability is enabled on a partition of the address space, a data access to that partition can be cached, if a data cache is present in the system. When data cacheability is disabled, all access to that partition goes directly to the Avalon switch fabric. Bit 31 is not used to specify data cacheability, as it is in Nios II cores without MMUs. Virtual memory partitions that bypass the TLB have a default data cacheability property, as described in the above table, Virtual Memory Partitions. For partitions that are mapped through the TLB, data cacheability is controlled by the TLB on a per-page basis.

Non-I/O load and store instructions use the default data cacheability property. I/O load and store instructions are always noncacheable, so they ignore the default data cacheability property.

TLB Organization

A TLB functions as a cache for the operating system's page table. In Nios II processors with an MMU, one main TLB is shared by instruction and data accesses. The TLB is stored in on-chip RAM and handles translations for instruction fetches and instructions that perform data accesses.

The TLB is organized as an n-way set-associative cache. The software specifies the way (set) when loading a new entry.

Note: You can configure the number of TLB entries and the number of ways (set associativity) of the TLB with the Nios II Processor parameter editor in Qsys. By default, the TLB is a 16-way cache. The default number of entries depends on the target device, as follows:

- Cyclone III®, Stratix III®, Stratix IV—256 entries, requiring one M9K RAM

  For more information, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook*.

The operating system software is responsible for guaranteeing that multiple TLB entries do not map the same virtual address. The hardware behavior is undefined when multiple entries map the same virtual address.

Each TLB entry consists of a tag and data portion. This is analogous to the tag and data portion of instruction and data caches.

Refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook* for information about instruction and data caches.

The tag portion of a TLB entry contains information used when matching a virtual address to a TLB entry.

Table 3-3: TLB Tag Portion Contents

Field Name	Description
VPN	VPN is the virtual page number field. This field is compared with the top 20 bits of the virtual address.
PID	PID is the process identifier field. This field is compared with the value of the current process identifier stored in the tlbmisc control register, effectively extending the virtual address. The field size is configurable in the Nios_II Processor parameter editor, and can be between 8 and 14 bits.
G	G is the global flag. When G = 1, the PID is ignored in the TLB lookup.

The TLB data portion determines how to translate a matching virtual address to a physical address.

Table 3-4: TLB Data Portion Contents

Field Name	Description
PFN	PFN is the physical frame number field. This field specifies the upper bits of the physical address. The size of this field depends on the range of physical addresses present in the system. The maximum size is 20 bits.
C	C is the cacheable flag. Determines the default data cacheability of a page. Can be overridden for data accesses using I/O load and store family of Nios II instructions.
R	R is the readable flag. Allows load instructions to read a page.
W	W is the writable flag. Allows store instructions to write a page.
X	X is the executable flag. Allows instruction fetches from a page.

Note: Because there is no "valid bit" in the TLB entry, the operating system software invalidates the TLB by writing unique VPN values from the I/O partition of virtual addresses into each TLB entry.

Related Information

TLB Lookups

A TLB lookup attempts to convert a virtual address (VADDR) to a physical address (PADDR).

Example 3-1: TLB Lookup Algorithm for Instruction Fetches

```
if (VPN match && (G == 1 || PID match))
    if (X == 1)
        PADDR = concat(PFN, VADDR[11:0])
    else take TLB permission violation exception
else
    if (EH bit of status register == 1)
        take double TLB miss exception
    else
        take fast TLB miss exception
```

Example 3-2: TLB Lookup Algorithm for Data Access Operations

```
if (VPN match && (G == 1 || PID match))
    if ((load && R == 1) || (store && W == 1) || flushda)
        PADDR = concatenate(PFN, VADDR[11:0])
    else
        take TLB permission violation exception
else
    if (EH bit of status register == 1)
        take double TLB miss exception
    else
        take fast TLB miss exception
```

Refer to "Instruction-Related Exceptions" for information about TLB exceptions.

Related Information

Memory Protection Unit

The Nios II processor provides an MPU for operating systems and runtime environments that desire memory protection but do not require virtual memory management. For information about memory protection with virtual memory management, refer to the Memory Management Unit section.

When present and enabled, the MPU monitors all Nios II instruction fetches and data memory accesses to protect against errant software execution. The MPU is a hardware facility that system software uses to define memory regions and their associated access permissions. The MPU triggers an exception if software attempts to access a memory region in violation of its permissions, allowing you to intervene and handle the exception as appropriate. The precise exception effectively prevents the illegal access to memory.

The MPU extends the Nios II processor to support user mode and supervisor mode. Typically, system software runs in supervisor mode and end-user applications run in user mode, although all software can run in supervisor mode if desired. System software defines which MPU regions belong to supervisor mode and which belong to user mode.

Related Information

[Memory Management Unit](#) on page 3-2

Memory Regions

The MPU contains up to 32 instruction regions and 32 data regions. Each region is defined by the following attributes:

- Base address
- Region type
- Region index
- Region size or upper address limit
- Access permissions
- Default cacheability (data regions only)

Base Address

The base address specifies the lowest address of the region. The base address is aligned on a region-sized boundary. For example, a 4-KB region must have a base address that is a multiple of 4 KB. If the base address is not properly aligned, the behavior is undefined.

Region Type

Each region is identified as either an instruction region or a data region.

Region Index

Each region has an index ranging from zero to the number of regions of its region type minus one. Index zero has the highest priority.

Region Size or Upper Address Limit

A Qsys generation-time option controls whether the amount of memory in the region is defined by size or upper address limit. The size is an integer power of two bytes. The limit is the highest address of the region plus one. The minimum supported region size is 256 bytes but can be configured for larger minimum sizes to save logic resources. The maximum supported region size equals the Nios II address space (a function of the address ranges of slaves connected to the Nios II masters). Any access outside of the Nios II address space is considered not to match any region and triggers an MPU region violation exception.

When regions are defined by size, the size is encoded as a binary mask to facilitate the following MPU region address range matching:

```
(address & region_mask) == region_base_address
```

When regions are defined by limit, the limit is encoded as an unsigned integer to facilitate the following MPU region address range matching:

```
(address >= region_base) && (address < region_limit)
```

The region limit uses a less-than instead of a less-than-or-equal-to comparison because less-than provides a more efficient implementation. The limit is one bit larger than the address so that full address range may be included in a range. Defining the region by limit results in slower and larger address range match logic than defining by size but allows finer granularity in region sizes.

Access Permissions

The access permissions consist of execute permissions for instruction regions and read/write permissions for data regions. Any instruction that performs a memory access that violates the access permissions triggers an exception. Additionally, any instruction that performs a memory access that does not match any region triggers an exception.

Default Cacheability

The default cacheability specifies whether normal load and store instructions access the data cache or bypass the data cache. The default cacheability is only present for data regions. You can override the default cacheability by using the `ldio` or `stio` instructions. The bit-31 cache and Peripheral Region featurs are available when the MMU is not present.

Refer to the Cache Memory section for more information on cache bypass and Peripheral Region.

Related Information
Cache Memory on page 3-60

Overlapping Regions

The memory addresses of regions can overlap. Overlapping regions have several uses including placing markers or small holes inside of a larger region. For example, the stack and heap may be located in the same region, growing from opposite ends of the address range. To detect stack/heap overflows, you can define a small region between the stack and heap with no access permissions and assign it a higher priority than the larger region. Any access attempts to the hole region trigger an exception informing system software about the stack/heap overflow.

If regions overlap so that a particular access matches more than one region, the region with the highest priority (lowest index) determines the access permissions and default cacheability.

Enabling the MPU

The MPU is disabled on system reset. System software enables and disables the MPU by writing to a control register. Before enabling the MPU, you must create at least one instruction and one data region, otherwise unexpected results can occur. Refer to the Working with the MPU section for more information.

Related Information
Working with the MPU on page 3-33

Registers

The Nios II register set includes general-purpose registers and control registers. In addition, the Nios II/f core can optionally have shadow register sets. This section discusses each register type.

General-Purpose Registers

The Nios II architecture provides thirty-two 32-bit general-purpose registers, `r0` through `r31`. Some registers have names recognized by the assembler. For example, the `zero` register (`r0`) always returns the value zero, and writing to `zero` has no effect. The `ra` register (`r31`) holds the return address used by procedure calls and is implicitly accessed by the `call`, `callr` and `ret` instructions. C and C++ compilers use a common procedure-call convention, assigning specific meaning to registers `r1` through `r23` and `r26` through `r28`.

Table 3-5: The Nios II General-Purpose Registers

Register	Name	Function	Register	Name	Function
r0	zero	0x00000000	r16		Callee-saved register
r1	at	Assembler temporary	r17		Callee-saved register
r2		Return value	r18		Callee-saved register
r3		Return value	r19		Callee-saved register
r4		Register arguments	r20		Callee-saved register
r5		Register arguments	r21		Callee-saved register
r6		Register arguments	r22		Callee-saved register
r7		Register arguments	r23		Callee-saved register
r8		Caller-saved register	r24	et	Exception temporary
r9		Caller-saved register	r25	bt	Breakpoint temporary
r10		Caller-saved register	r26	gp	Global pointer
r11		Caller-saved register	r27	sp	Stack pointer
r12		Caller-saved register	r28	fp	Frame pointer
r13		Caller-saved register	r29	ea	Exception return address
r14		Caller-saved register	r30	sstatus	Status register
r15		Caller-saved register	r31	ra	Return address

Note: r25 is used exclusively by the JTAG debug module. It is used as the breakpoint temporary (bt) register in the normal register set. In shadow register sets, r25 is reserved.

Note: r30 is used as the breakpoint return address (ba) in the normal register set, and as the shadow register set status (sstatus) in each shadow register set. For details about sstatus, refer to The Status Register section.

For more information, refer to the *Application Binary Interface* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Control Registers

Control registers report the status and change the behavior of the processor. Control registers are accessed differently than the general-purpose registers. The special instructions rdctl and wrctl provide the only means to read and write to the control registers and are only available in supervisor mode.

Note: When writing to control registers, all undefined bits must be written as zero.

The Nios II architecture supports up to 32 control registers. All nonreserved control registers have names recognized by the assembler.

Table 3-6: Control Register Names and Bits

Register	Name	Register Contents
0	status	Refer to **The status Register** on page 3-13
1	estatus	Refer to **The estatus Register** on page 3-15
2	bstatus	Refer to **The bstatus Register**
3	ienable	Internal interrupt-enable bits **The ienable Register** Available only when the external interrupt controller interface is not present. Otherwise reserved.
4	ipending	Pending internal interrupt bits **The ipending Register** Available only when the external interrupt controller interface is not present. Otherwise reserved.

15	mpuacc	Refer to **The mpuacc Register** for MASK variations table. Available only when the MPU is present. Otherwise reserved.
16–31	Reserved	Reserved

The following sections describe the nonreserved control registers.

The status Register

The value in the status register determines the state of the Nios II processor. All status bits are set to predefined values at processor reset. Some bits are exclusively used by and available only to certain features of the processor, such as the MMU, MPU or external interrupt controller (EIC) interface.

Table 3-8: status Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

Table 3-9: status Control Register Field Descriptions

Bit	Description	Access	Reset	Available
RSIE	RSIE is the register set interrupt-enable bit. When set to 1, this bit allows the processor to service external interrupts requesting the register set that is currently in use. When set to 0, this bit disallows servicing of such interrupts.	Read/Write	1	EIC interface and shadow register sets only[5]
NMI	NMI is the nonmaskable interrupt mode bit. The processor sets NMI to 1 when it takes a nonmaskable interrupt.	Read	0	EIC interface only[8]

PRS	PRS is the previous register set field. The processor copies the CRS field to the PRS field upon one of the following events:
	
	• In a processor with no MMU, on any exception
	• In a processor with an MMU, on one of the following:
	
	  Break exception
	
	  Nonbreak exception when status.EH is zero
	
	  The processor copies CRS to PRS immediately after copying the status register to estatus, bstatus or sstatus.
	
	  The number of significant bits in the CRS and PRS fields depends on the number of shadow register sets implemented in the Nios II core. The value of CRS and PRS can range from 0 to n-1, where n is the number of implemented register sets. The processor core implements the number of significant bits needed to represent n-1. Unused high-order bits are always read as 0, and must be written as 0.
	
	  1 Ensure that system software writes only valid register set numbers to the PRS field. Processor behavior is undefined with an unimplemented register set number.
		Read/Write	0	Shadow register sets only[8]

---

[5] When this field is unimplemented, the field value always reads as 1, and the processor behaves accordingly.

Bit	Description	Access	Reset	Available
CRS	CRS is the current register set field. CRS indicates which register set is currently in use. Register set 0 is the normal register set, while register sets 1 and higher are shadow register sets. The processor sets CRS to zero on any noninterrupt exception. The number of significant bits in the CRS and PRS fields depends on the number of shadow register sets implemented in the Nios II core. Unused high-order bits are always read as 0, and must be written as 0.	Read[6]	0	Shadow register sets only[8]
IL	IL is the interrupt level field. The IL field controls what level of external maskable interrupts can be serviced. The processor services a maskable interrupt only if its requested interrupt level is greater than IL.	Read/Write	0	EIC interface only[8]
IH	IH is the interrupt handler mode bit. The processor sets IH to one when it takes an external interrupt.	Read/Write	0	EIC interface only[8]
EH[7]	EH is the exception handler mode bit. The processor sets EH to one when an exception occurs (including breaks). Software clears EH to zero when ready to handle exceptions again. EH is used by the MMU to determine whether a TLB miss exception is a fast TLB miss or a double TLB miss. In systems without an MMU, EH is always zero.	Read/Write	0	MMU or ECC only[8]
U[7]	U is the user mode bit. When U = 1, the processor operates in user mode. When U = 0, the processor operates in supervisor mode. In systems without an MMU, U is always zero.	Read/Write	0	MMU or MPU only[8]
PIE	PIE is the processor interrupt-enable bit. When PIE = 0, internal and maskable external interrupts and noninterrupt exceptions are ignored. When PIE = 1, internal and maskable external interrupts can be taken, depending on the status of the interrupt controller. Noninterrupt exceptions are unaffected by PIE.	Read/Write	0	Always

Related Information
External Interrupt Controller Interface on page 3-43

The estatus Register

The estatus register holds a saved copy of the status register during nonbreak exception processing.

---

[6] The CRS field is read-only. For information about manually changing register sets, refer to the External Interrupt Controller Interface section.

[7] The state where both EH and U are one is illegal and causes undefined results.

[8] When this field is unimplemented, the field value always reads as 0, and the processor behaves accordingly.

Table 3-10: estatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

All fields in the `estatus` register have read/write access. All fields reset to 0.

When the Nios II processor takes an interrupt, if `status.eh` is zero (that is, the MMU is in nonexception mode), the processor copies the contents of the `status` register to `estatus`.

Note: If shadow register sets are implemented, and the interrupt requests a shadow register set, the Nios II processor copies status to `sstatus`, not to `estatus`.

For details about the `sstatus` register, refer to The sstatus Register section.

The exception handler can examine `estatus` to determine the pre-exception status of the processor. When returning from an exception, the `eret` instruction restores the pre-exception value of `status`. The instruction restores the pre-exception value by copying either `estatus` or `sstatus` back to `status`, depending on the value of `status.CRS`.

Refer to the Exception Processing section for more information.

Related Information

- **Exception Processing** on page 3-38
- **The sstatus Register** on page 3-31

The bstatus Register

The `bstatus` register holds a saved copy of the `status` register during break exception processing.

Table 3-11: btatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

All fields in the `bstatus` register have read/write access. All fields reset to 0.

The Status Control Register Field Description table describes the details of the fields defined in the `bstatus` register.

When a break occurs, the value of the `status` register is copied into `bstatus`. Using `bstatus`, the debugger can restore the `status` register to the value prior to the break. The `bret` instruction causes the processor to copy `bstatus` back to `status`. Refer to the Processing a Break section for more information.

The ienable Register

The `ienable` register controls the handling of internal hardware interrupts. Each bit of the `ienable` register corresponds to one of the interrupt inputs, `irq0` through `irq31`. A value of one in bit n means that the corresponding `irqn` interrupt is enabled; a bit value of zero means that the corresponding interrupt is disabled. Refer to the Exception Processing section for more information.

Note: When the internal interrupt controller is not implemented, the value of the `ienable` register is always 0.

The ipending Register

The value of the `ipending` register indicates the value of the enabled interrupt signals driven into the processor. A value of one in bit n means that the corresponding `irq` n input is asserted and enabled in the `ienable` register. Writing a value to the `ipending` register has no effect.

Note: The `ipending` register is present only when the internal interrupt controller is implemented.

The cpuid Register

The `cpuid` register holds a constant value that you define in the Nios II Processor parameter editor to uniquely identify each processor in a multiprocessor system. In Qsys, unique values must be assigned manually. Writing to the `cpuid` register has no effect.

The exception Register

Nios II/f Processor provides information useful to system software for exception processing in the exception and badaddr registers when an exception occurs.

Note: The exception register is not enabled for Nios II/e core.

For information about controlling the extra exception information option, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

Table 3-12: exception Control Register Fields

Bit Fields

Programming Model on page 3-1

The pteaddr Register

The pteaddr register contains the virtual address of the operating system's page table and is only available in systems with an MMU. The pteaddr register layout accelerates fast TLB miss exception handling.

Table 3-14: pteaddr Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTBASE															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VPN														Rsvd	

Table 3-15: pteaddr Control Register Field Descriptions

Field	Description	Access	Reset	Available
PTBASE	PTBASE is the base virtual address of the page table.	Read/Write	0	Only with MMU
VPN	VPN is the virtual page number. VPN can be set by both hardware and software.	Read/Write	0	Only with MMU

Software writes to the PTBASE field when switching processes. Hardware never writes to the PTBASE field.

Software writes to the VPN field when writing a TLB entry. Hardware writes to the VPN field on a fast TLB miss exception, a TLB permission violation exception, or on a TLB read operation. The VPN field is not written on any exceptions taken when an exception is already active, that is, when status.EH is already one.

The tlbacc Register

The `tlbacc` register is used to access TLB entries and is only available in systems with an MMU. The `tlbacc` register holds values that software will write into a TLB entry or has previously read from a TLB entry. The `tlbacc` register provides access to only a portion of a complete TLB entry. `pteaddr.VPN` and `tlbmisc.PID` hold the remaining TLB entry fields.

Table 3-16: tlbacc Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IG							C	R	W	X	G	PFN			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PFN															

Issuing a `wrctl` instruction to the `tlbacc` register writes the `tlbacc` register with the specified value. If `tlbmisc.WE = 1`, the `wrctl` instruction also initiates a TLB write operation, which writes a TLB entry. The TLB entry written is specified by the line portion of `pteaddr.VPN` and the `tlbmisc.WAY` field. The value written is specified by the value written into `tlbacc` along with the values of `pteaddr.VPN` and `tlbmisc.PID`. A TLB write operation also increments `tlbmisc.WAY`, allowing software to quickly modify TLB entries.

Issuing a `rdctl` instruction to the `tlbacc` register returns the value of the `tlbacc` register. The `tlbacc` register is written by hardware when software triggers a TLB read operation (that is, when `wrctl` sets `tlbmisc.RD` to one).

Table 3-17: tlbacc Control Register Field Descriptions

Field	Description	Access	Reset	Available
IG	`IG` is ignored by hardware and available to hold operating system specific information. Read as zero but can be written as nonzero.	Read/ Write	0	Only with MMU
C	`C` is the data cacheable flag. When `C = 0`, data accesses are uncacheable. When `C = 1`, data accesses are cacheable.	Read/ Write	0	Only with MMU
R	`R` is the readable flag. When `R = 0`, load instructions are not allowed to access memory. When `R = 1`, load instructions are allowed to access memory.	Read/ Write	0	Only with MMU
W	`W` is the writable flag. When `W = 0`, store instructions are not allowed to access memory. When `W = 1`, store instructions are allowed to access memory.	Read/ Write	0	Only with MMU
X	`X` is the executable flag. When `X = 0`, instructions are not allowed to execute. When `X = 1`, instructions are allowed to execute.	Read/ Write	0	Only with MMU
G	`G` is the global flag. When `G = 0`, `tlbmisc.PID` is included in the TLB lookup. When `G = 1`, `tlbmisc.PID` is ignored and only the virtual page number is used in the TLB lookup.	Read/ Write	0	Only with MMU

Field	Description	Access	Reset	Available
PFN	PFN is the physical frame number field. All unused upper bits must be zero.	Read/ Write	0	Only with MMU

The `tlbacc` register format is the recommended format for entries in the operating system page table. The IG bits are ignored by the hardware on `wrctl` to `tlbacc` and read back as zero on `rdctl` from `tlbacc`. The operating system can use the IG bits to hold operating system specific information without having to clear these bits to zero on a TLB write operation.

The tlbmisc Register

The `tlbmisc` register contains the remaining TLB-related fields and is only available in systems with an MMU.

Table 3-18: tlbmisc Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							EE	WAY				RD	WE	PID	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PID												DBL	BAD	PERM	D

Table 3-19: tlbmisc Control Register Field Descriptions

Field	Description	Access	Reset	Available
EE	If this field is a 1, a software-triggered ECC error (1, 2, or 3 bit error) occurred because software initiated a TLB read operation. Only set this field to 1 if `CONFIG.ECCEN` is 1.	Read/ Write	0	Only with MMU and EEC
WAY	The WAY field controls the mapping from the VPN to a particular TLB entry. This field size is variable. Unused upper bits must be written as zero.	Read/ Write	0	Only with MMU
RD	RD is the read flag. Setting RD to one triggers a TLB read operation.	Write	0	Only with MMU
WE	WE is the TLB write enable flag. When WE = 1, a write to `tlbacc` writes through to a TLB entry.	Read/ Write	0	Only with MMU
PID	PID is the process identifier field. This field size is variable. Unused upper bits must be written as zero.	Read/ Write	0	Only with MMU
DBL	DBL is the double TLB miss exception flag.	Read	0	Only with MMU
BAD	BAD is the bad virtual address exception flag.	Read	0	Only with MMU
PERM	PERM is the TLB permission violation exception flag.	Read	0	Only with MMU

Field	Description	Access	Reset	Available
D	D is the data access exception flag. When D = 1, the exception is a data access exception. When D = 0, the exception is an instruction access exception.	Read	0	Only with MMU

For DBL, BAD, and PERM fields you can also use exception.CAUSE to determine these exceptions.

The following sections provide more information about the tlbmisc fields.

The RD Flag

System software triggers a TLB read operation by setting tlbmisc.RD (with a wrctl instruction). A TLB read operation loads the following register fields with the contents of a TLB entry:

- The tag portion of pteaddr.VPN
- tlbmisc.PID
- The tlbacc register

The TLB entry to be read is specified by the following values:

- the line portion of pteaddr.VPN
- tlbmisc.WAY

When system software changes the fields that specify the TLB entry, there is no immediate effect on pteaddr.VPN, tlbmisc.PID, or the tlbacc register. The registers retain their previous values until the next TLB read operation is initiated. For example, when the operating system sets pteaddr.VPN to a new value, the contents of tlbacc continues to reflect the previous TLB entry. tlbacc does not contain the new TLB entry until after an explicit TLB read.

The WE Flag

When WE = 1, a write to tlbacc writes the tlbacc register and a TLB entry. When WE = 0, a write to tlbacc only writes the tlbacc register.

Hardware sets the WE flag to one on a TLB permission violation exception, and on a TLB miss exception when status.EH = 0. When a TLB write operation writes the tlbacc register, the write operation also writes to a TLB entry when WE = 1.

The WAY Field

The WAY field controls the mapping from the VPN to a particular TLB entry. WAY specifies the set to be written to in the TLB. The MMU increments WAY when system software performs a TLB write operation. Unused upper bits in WAY must be written as zero.

Note: The number of ways (sets) is configurable in Qsys at generation time, up to a maximum of 16.

The PID Field

PID is a unique identifier for the current process that effectively extends the virtual address. The process identifier can be less than 14 bits. Any unused upper bits must be zero.

tlbmisc.PID contains the PID field from a TLB tag. The operating system must set the PID field when switching processes, and before each TLB write operation.

Note: Use of the process identifier is optional. To implement memory management without process identifiers, clear tlbmisc.PID to zero. Without a process identifier, all processes share the same virtual address space.

The MMU sets `tlbmisc.PID` on a TLB read operation. When the software triggers a TLB read, by setting `tlbmisc.RD` to one with the `wrctl` instruction, the `PID` value read from the TLB has priority over the value written by the `wrctl` instruction.

The size of the `PID` field is configured in Qsys at system generation, and can be from 8 to 14 bits. If system software defines a process identifier smaller than the `PID` field, unused upper bits must be written as zero.

The DBL Flag

During a general exception, the processor sets `DBL` to one when a double TLB miss condition exists. Otherwise, the processor clears `DBL` to zero.

The `DBL` flag indicates whether the most recent exception is a double TLB miss condition. When a general exception occurs, the MMU sets `DBL` to one if a double TLB miss is detected, and clears `DBL` to zero otherwise.

The BAD Flag

During a general exception, the processor sets `BAD` to one when a bad virtual address condition exists, and clears `BAD` to zero otherwise. The following exceptions set the `BAD` flag to one:

- Supervisor-only instruction address
- Supervisor-only data address
- Misaligned data address
- Misaligned destination address

Refer to Nios II Exceptions (In Decreasing Priority Order) table in the "Exception Overview" section for more information on these exceptions.

Related Information

Exception Overview on page 3-39

The PERM Flag

During a general exception, the processor sets `PERM` to one for a TLB permission violation exception, and clears `PERM` to zero otherwise.

The D Flag

The `D` flag indicates whether the exception is an instruction access exception or a data access exception. During a general exception, the processor sets `D` to one when the exception is related to a data access, and clears `D` to zero for all other nonbreak exceptions.

The following exceptions set the `D` flag to one:

- Fast TLB miss (data)
- Double TLB miss (data)
- TLB permission violation (read or write)
- Misaligned data address
- Supervisor-only data address

The badaddr Register

Nios II/f processor provides information useful to system software for exception processing in the exception and badaddr registers when an exception occurs.

Note: The exception register is not enabled for Nios II/e.

When an exception occurs in Nios II/f processor, the `badaddr` register contains the byte instruction or data address associated with certain exceptions at the time the exception occurred. The Nios II Exceptions Table lists which exceptions write the `badaddr` register along with the value written.

Table 3-20: badaddr Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BADDR															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BADDR															

Table 3-21: badaddr Control Register Field Descriptions

Field	Description	Access	Reset	Available
BADDR	BADDR contains the byte instruction address or data address associated with an exception when certain exceptions occur. The Address column of the Nios II Exceptions Table lists which exceptions write the BADDR field.	Read	0	Only with Nios II/f

The `BADDR` field allows up to a 32-bit instruction address or data address. If an MMU or MPU is present, the `BADDR` field is 32 bits because MMU and MPU instruction and data addresses are always full 32-bit values. When an MMU is present, the `BADDR` field contains the virtual address.

If there is no MMU or MPU and the Nios II address space is less than 32 bits, unused high-order bits are written and read as zero. If there is no MMU, bit 31 of a data address (used to bypass the data cache) is always zero in the `BADDR` field.

Related Information

- **Exception Overview** on page 3-39
- **Programming Model** on page 3-1

The config Register

The `config` register configures Nios II runtime behaviors that do not need to be preserved during exception processing (in contrast to the information in the `status` register).

Table 3-22: config Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												ECCE XE	ECCE N	ANI	PE

Table 3-23: config Control Register Field Descriptions

Field	Description	Access	Reset	Available
ANI	ANI is the automatic nested interrupt mode bit. If ANI is set to zero, the processor clears status.PIE on each interrupt, disabling fast nested interrupts. If ANI is set to one, the processor keeps status.PIE set to one at the time of an interrupt, enabling fast nested interrupts. If the EIC interface and shadow register sets are not implemented in the Nios II core, ANI always reads as zero, disabling fast nested interrupts.	Read/Write	0	Only with the EIC interface and shadow register sets
ECCEXE	ECCEX is the ECC error exception enable bit. When ECCEXE = 1, the Nios II processor generates ECC error exceptions.	Read/Write	0	Only with ECC
ECCEN	ECCEN is the ECC enable bit. When ECCEN = 0, the Nios II processor ignores all ECC errors. When ECCEN = 1, the Nios II processor recovers all recoverable ECC errors.	Read/Write	0	Only with ECC
PE	PE is the memory protection enable bit. When PE =1, the MPU is enabled. When PE = 0, the MPU is disabled. In systems without an MPU, PE is always zero.	Read/Write	0	Only with MPU

The mpubase Register

The mpubase register works in conjunction with the mpuacc register to set and retrieve MPU region information and is only available in systems with an MPU.

Table 3-24: mpubase Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BASE[10]															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE[10]								0		INDEX[9]					D

Table 3-25: mpubase Control Register Field Descriptions

Field	Description	Access	Reset	Available
BASE	BASE is the base memory address of the region identified by the INDEX and D fields.	Read/Write	0	Only with MPU

---

[9] This field size is variable. Unused upper bits must be written as zero.

[10] This field size is variable. Unused upper bits and unused lower bits must be written as zero.

Field	Description	Access	Reset	Available
INDEX	INDEX is the region index number.	Read/Write	0	Only with MPU
D	D is the region access bit. When D =1, INDEX refers to a data region. When D = 0, INDEX refers to an instruction region.	Read/Write	0	Only with MPU

The BASE field specifies the base address of an MPU region. The 25-bit BASE field corresponds to bits 6 through 30 of the base address, making the base address always a multiple of 64 bytes. If the minimum region size set in Qsys at generation time is larger than 64 bytes, unused low-order bits of the BASE field must be written as zero and are read as zero. For example, if the minimum region size is 1024 bytes, the four least-significant bits of the BASE field (bits 6 though 9 of the mpubase register) must be zero. Similarly, if the Nios II address space is less than 31 bits, unused high-order bits must also be written as zero and are read as zero.

The INDEX and D fields specify the region information to access when an MPU region read or write operation is performed. The D field specifies whether the region is a data region or an instruction region. The INDEX field specifies which of the 32 data or instruction regions to access. If there are fewer than 32 instruction or 32 data regions, unused high-order bits must be written as zero and are read as zero.

Refer to the MPU Region Read and Write Operations section for more information on MPU region read and write operations.

Related Information

MPU Region Read and Write Operations on page 3-33

The mpuacc Register

The mpuacc register works in conjunction with the mpubase register to set and retrieve MPU region information and is only available in systems with an MPU. The mpuacc register consists of attributes that will be set or have been retrieved which define the MPU region. The mpuacc register only holds a portion of the attributes that define an MPU region. The remaining portion of the MPU region definition is held by the BASE field of the mpubase register.

A Qsys generation-time option controls whether the mpuacc register contains a MASK or LIMIT field.

Table 3-26: mpuacc Control Register Fields for MASK Variation

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[11]															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[11]									MT		PERM			RD	WR

Table 3-27: mpuacc Control Register Fields for LIMIT Variation

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Fields															
LIMIT[11]															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LIMIT[11]									MT		PERM			RD	WR

Table 3-28: mpuacc Control Register Field Descriptions

Field	Description	Access	Reset	Available
MASK	MASK specifies the size of the region.	Read/ Write	0	Only with MPU
LIMIT	LIMIT specifies the upper address limit of the region.	Read/ Write	0	Only with MPU
MT	(MT) Memory Type: • 0 = peripheral (non-cacheable, non-write bufferable) • 1 = normal (cacheable, write bufferable) • 2 = device (non-cacheable, write bufferable) • 3 = reserved	Read/ Write	0	Only with MPU
PERM	PERM specifies the access permissions for the region.	Read/ Write	0	Only with MPU
RD	RD is the read region flag. When RD = 1, wrctl instructions to the mpuacc register perform a read operation.	Write	0	Only with MPU
WR	WR is the write region flag. When WR = 1, wrctl instructions to the mpuacc register perform a write operation.	Write	0	Only with MPU

The MASK and LIMIT fields are mutually exclusive. Refer to mpucc Control Register Field for MASK Variation Table and mpuacc Control Register Field for LIMIT Variation Table.

The following sections provide more information about the mpuacc fields.

Related Information

The MASK Field

When the amount of memory reserved for a region is defined by size, the MASK field specifies the size of the memory region. The MASK field is the same number of bits as the BASE field of the mpubase register.

Note: Unused high-order or low-order bits must be written as zero and are read as zero.

---

[11] This field size is variable. Unused upper bits and unused lower bits must be written as zero.

MASK Region Size Encodings Table lists the MASK field encodings for all possible region sizes in a full 31-bit byte address space.

Table 3-29: MASK Region Size Encodings

MASK Encoding	Region Size
0x1FFFFFC	256 bytes
0x1FFFFF8	512 bytes
0x1FFFFF0	1 KB
0x1FFFFE0	2 KB
0x1FFFFC0	4 KB
0x1FFFF80	8 KB
0x1FFFF00	16 KB
0x1FFFE00	32 KB
0x1FFFC00	64 KB
0x1FFF800	128 KB
0x1FFF000	256 KB
0x1FFE000	512 KB
0x1FFC000	1 MB
0x1FF8000	2 MB
0x1FF0000	4 MB
0x1FE0000	8 MB
0x1FC0000	16 MB
0x1F80000	32 MB
0x1F00000	64 MB
0x1E00000	128 MB
0x1C00000	256 MB
0x1800000	512 MB
0x1000000	1 GB
0x0000000	2 GB

The MASK field contains the following value, where region_size is in bytes:

```
MASK = 0x1FFFFFF << log2(region_size >> 6)
```

The LIMIT Field

When the amount of memory reserved for a region is defined by an upper address limit, the LIMIT field specifies the upper address of the memory region plus one. For example, to achieve a memory range for byte addresses 0x4000 to 0x4fff with a 256 byte minimum region size, the BASE field of the mpubase

register is set to `0x40` (`0x4000 >> 6`) and the `LIMIT` field is set to `0x50` (`0x5000 >> 6`). Because the `LIMIT` field is one more bit than the number of bits of the `BASE` field of the `mpubase` register, bit 31 of the `mpuacc` register is available to the `LIMIT` field.

The C Flag

The `C` flag determines the default data cacheability of an MPU region. The `C` flag only applies to data regions. For instruction regions, the `C` bit must be written with 0 and is always read as 0.

When data cacheability is enabled on a data region, a data access to that region can be cached, if a data cache is present in the system. You can override the default cacheability and force an address to noncacheable with an `ldio` or `stio` instruction.

Note: The bit 31 cache bypass feature is supported when the MPU is present. Refer to the Cache memory section for more information on cache bypass.

Related Information

Cache Memory on page 3-60

The MT Flag

The `MT` flag determines the default memory type of an MPU data region. . The `MT` flag only applies to data regions. For instruction regions, the `MT` bit must be written with 0 for instruction regions and is always read as 0.

When data cacheability is enabled on a data region, a data access to that region can be cached, if a data cache is present in the system. You can override the default cacheability and force an address to noncacheable with an `ldio` or `stio` instruction. The encoding of the MT field is setup to be backwards-compatible with the Nios II Classic core MPU where bit 5 of MPUACC contains the cacheable bit (0 = non-cacheable, 1 = cacheable) and bit 6 is zero.

Note: The bit 31 cache bypass and peripheral region features are supported when the MPU is present. Refer to the Cache memory section for more information on cache bypass.

The PERM Field

The `PERM` field specifies the allowed access permissions.

Table 3-30: Instruction Region Permission Values

Value	Supervisor Permissions	User Permissions
0	None	None
1	Execute	None
2	Execute	Execute

Table 3-31: Data Region Permission Values

Value	Supervisor Permissions	User Permissions
0	None	None
1	Read	None
2	Read	Read
4	Read/Write	None

Value	Supervisor Permissions	User Permissions
5	Read/Write	Read
6	Read/Write	Read/Write

Note: Unlisted table values are reserved and must not be used. If you use reserved values, the resulting behavior is undefined.

The RD Flag

Setting the RD flag signifies that an MPU region read operation should be performed when a wrctl instruction is issued to the mpuacc register. Refer to the MPU Region Read and Write Operations section for more information. The RD flag always returns 0 when read by a rdctl instruction.

Related Information

MPU Region Read and Write Operations on page 3-33

The WR Flag

Setting the WR flag signifies that an MPU region write operation should be performed when a wrctl instruction is issued to the mpuacc register. Refer to the MPU Region Read and Write Operations section for more information. The WR flag always returns 0 when read by a rdctl instruction.

Note: Setting both the RD and WR flags to one results in undefined behavior.

Related Information

MPU Region Read and Write Operations on page 3-33

The eccinj Register

The eccinj register injects 1 and 2 bit errors to the Nios II processor's internal RAM blocks that support ECC. Injecting errors allows the software to test the ECC error exception handling code. The error(s) are injected in the data bits, not the parity bits. The eccinj register is only available when ECC is present.

Table 3-32: eccinj Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved										DC WB		DTCM 3		DTCM 2	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DTCM 1		DTCM 0		TLB		DC DAT		DC TAG		ICDAT		ICTAG		RF	

Software writes 0x1 to inject a 1 bit ECC error or 0x2 to inject a 2-bit ECC error to the RAM field. Hardware sets the value of the inject field to 0x0 after the error injection has occurred.

Table 3-33: eccinj Control Register Field Descriptions

Field	Description	Access	Reset	Available
RF	Inject an ECC error in the register file's RAM.	Read/ Write	0	Only with ECC

Field	Description	Access	Reset	Available
ICTAG	Inject an ECC error in the instruction cache Tag RAM.	Read/Write	0	Only with ECC
ICDAT	Inject an ECC error in the instruction cache data RAM.	Read/Write	0	Only with ECC
DCTAG	Inject ECC error in data cache tag RAM.	Read/Write	0	
DCDAT	Inject an ECC error in the data cache data RAM. Injection occurs on next store instruction that writes the data cache or the next line fill.	Read/Write	0	
TLB	Inject an ECC error in the MMU TLB RAM. Errors are injected in the tag portion of the VPN field.	Read/Write	0	Only with ECC
DTCM0	Inject ECC error in DTCM0. Injection occurs on next store instruction that writes this DTCM.	Read/Write	0	
DTCM1	Inject ECC error in DTCM1. Injection occurs on next store instruction that writes this DTCM.	Read/Write	0	
DTCM2	Inject ECC error in DTCM2. Injection occurs on next store instruction that writes this DTCM.	Read/Write	0	
DTCM3	Inject ECC error in DTCM3. Injection occurs on next store instruction that writes this DTCM.	Read/Write	0	
DC WB	Inject ECC error in data cache victim line buffer RAM. Injection occurs on the first word written into the victim buffer RAM when a dirty line is being written back.	Read/Write	0	

Refer to "Working with ECC" for more information about when errors are injected.

Related Information
Working with ECC on page 3-35

Shadow Register Sets

The Nios II processor can optionally have one or more shadow register sets. A shadow register set is a complete alternate set of Nios II general-purpose registers, which can be used to maintain a separate runtime context for an interrupt service routine (ISR).

When shadow register sets are implemented, status.CRS indicates the register set currently in use. A Nios II core can have up to 63 shadow register sets. If n is the configured number of shadow register sets, the shadow register sets are numbered from 1 to n. Register set 0 is the normal register set.

A shadow register set behaves precisely the same as the normal register set. The register set currently in use can only be determined by examining status.CRS.

Note: When shadow register sets and the EIC interface are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or later. Earlier versions have an implementation of the eret instruction that is incompatible with shadow register sets.

Shadow register sets are typically used in conjunction with the EIC interface. This combination can substantially reduce interrupt latency.

For details of EIC interface usage, refer to the Exception Processing section.

System software can read from and write to any shadow register set by setting `status.PRS` and using the `rdprs` and `wrprs` instructions.

For details of the `rdprs` and `wrprs` instructions, refer to the *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook.*

Related Information

- **Instruction Set Reference** on page 8-1
- **Exception Processing** on page 3-38

The sstatus Register

The value in the `sstatus` register preserves the state of the Nios II processor during external interrupt handling. The value of `sstatus` is undefined at processor reset. Some bits are exclusively used by and available only to certain features of the processor.

The `sstatus` register is physically stored in general-purpose register `r30` in each shadow register set. The normal register set does not have an `sstatus` register, but each shadow register set has a separate `sstatus` register.

Table 3-34: sstatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRS	Reserved							RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

Table 3-35: sstatus Control Register Field Descriptions

Bit	Description	Access	Reset	Available
SRS[12]	SRS is the switched register set bit. The processor sets SRS to 1 when an external interrupt occurs, if the interrupt required the processor to switch to a different register set.	Read/Write	Undefined	EIC interface and shadow register sets only
RSIE	RSIE is the register set interrupt-enable bit. When set to 1, this bit allows the processor to service external interrupts requesting the register set that is currently in use. When set to 0, this bit disallows servicing of such interrupts.	Read/Write	Undefined	[13]

---

[12] If the EIC interface and shadow register sets are not present, SRS always reads as 0, and the processor behaves accordingly.

Bit	Description	Access	Reset	Available
NMI	NMI is the nonmaskable interrupt mode bit. The processor sets NMI to 1 when it takes a nonmaskable interrupt.	Read/Write	Undefined	(13)
PRS	(13)	Read/Write	Undefined	(13)
CRS	(13)	Read/Write	Undefined	(13)
IL	(13)	Read/Write	Undefined	(13)
IH	(13)	Read/Write	Undefined	(13)
EH	(13)	Read/Write	Undefined	(13)
U	(13)	Read/Write	Undefined	(13)
PIE	(13)	Read/Write	Undefined	(13)

The sstatus register is present in the Nios II core if both the EIC interface and shadow register sets are implemented. There is one copy of sstatus for each shadow register set.

When the Nios II processor takes an interrupt, if a shadow register set is requested (RRS = 0) and the MMU is not in exception handler mode (status.EH = 0), the processor copies status to sstatus.

For details about RRS, refer to "Requested Register Set".

For details about status.EH, refer to the Nios II Processor Status After Taking Exceptions Table.

Related Information

- **The status Register** on page 3-13
- **Exceptions and Processor Status** on page 3-53
- **Requested Register Set** on page 3-44
- **The status Register** on page 3-13

Changing Register Sets

Modifying status.CRS immediately switches the Nios II processor to another register set. However, software cannot write to status.CRS directly. To modify status.CRS, insert the desired value into the saved copy of the status register, and then execute the eret instruction, as follows:

- If the processor is currently running in the normal register set, insert the new register set number in estatus.CRS, and execute eret.
- If the processor is currently running in a shadow register set, insert the new register set number in sstatus.CRS, and execute eret.

---

(13) Refer to the status Control Register Field Descriptions Table

Before executing `eret` to change the register set, system software must set individual external interrupt masks correctly to ensure that registers in the shadow register set cannot be corrupted. If an interrupt is assigned to the register set, system software must ensure that one of the following conditions is true:

- The ISR is written to preserve register contents.
- The individual interrupt is disabled. The method for disabling an individual external interrupt is specific to the EIC implementation.

Stacks and Shadow Register Sets

Depending on system requirements, the system software can create a dedicated stack for each register set, or share a stack among several register sets. If a stack is shared, the system software must copy the stack pointer each time the register set changes. Use the `rdprs` instruction to copy the stack register between the current register set and another register set.

Initialization with Shadow Register Sets

At initialization, system software must carry out the following tasks to ensure correct software functioning with shadow register sets:

- After the `gp` register is initialized in the normal register set, copy it to all shadow register sets, to ensure that all code can correctly address the small data sections.
- Copy the `zero` register from the normal register set to all shadow register sets, using the `wrprs` instruction.

Working with the MPU

This section provides a basic overview of MPU initialization and the MPU region read and write operations.

MPU Region Read and Write Operations

MPU region read and write operations are operations that access MPU region attributes through the `mpubase` and `mpuacc` control registers. The `mpubase.BASE`, `mpuacc.MASK`, `mpuacc.LIMIT`, `mpuacc.C`, and `mpuacc.PERM` fields comprise the MPU region attributes.

MPU region read operations retrieve the current values for the attributes of a region. Each MPU region read operation consists of the following actions:

- Execute a `wrctl` instruction to the `mpubase` register with the `mpubase.INDEX` and `mpubase.D` fields set to identify the MPU region.
- Execute a `wrctl` instruction to the `mpuacc` register with the `mpuacc.RD` field set to one and the `mpuacc.WR` field cleared to zero. This action loads the `mpubase` and `mpuacc` register values.
- Execute a `rdctl` instruction to the `mpubase` register to read the loaded the `mpubase` register value.
- Execute a `rdctl` instruction to the `mpuacc` register to read the loaded the `mpuacc` register value.

The MPU region read operation retrieves `mpubase.BASE`, `mpuacc.MASK` or `mpuacc.LIMIT`, `mpuacc.C`, and `mpuacc.PERM` values for the MPU region.

Note: Values for the `mpubase` register are not actually retrieved until the `wrctl` instruction to the `mpuacc` register is performed.

MPU region write operations set new values for the attributes of a region. Each MPU region write operation consists of the following actions:

- Execute a `wrctl` instruction to the `mpubase` register with the `mpubase.INDEX` and `mpubase.D` fields set to identify the MPU region.
- Execute a `wrctl` instruction to the `mpuacc` register with the `mpuacc.WR` field set to one and the `mpuacc.RD` field cleared to zero.

The MPU region write operation sets the values for `mpubase.BASE`, `mpuacc.MASK` or `mpuacc.LIMIT`, `mpuacc.C`, and `mpuacc.PERM` as the new attributes for the MPU region.

Normally, a `wrctl` instruction flushes the pipeline to guarantee that any side effects of writing control registers take effect immediately after the `wrctl` instruction completes execution. However, `wrctl` instructions to the `mpubase` and `mpuacc` control registers do not automatically flush the pipeline. Instead, system software is responsible for flushing the pipeline as needed (either by using a `flushp` instruction or a `wrctl` instruction to a register that does flush the pipeline). Because a context switch typically requires reprogramming the MPU regions for the new thread, flushing the pipeline on each `wrctl` instruction would create unnecessary overhead.

MPU Initialization

Your system software must provide a data structure that contains the region information described in the "Memory Regions" section of this chapter for each active thread. The data structure ideally contains two 32-bit values that correspond to the `mpubase` and `mpuacc` register formats.

The MPU is disabled on system reset. Before enabling the MPU, Altera recommends initializing all MPU regions. Enable desired instruction and data regions by writing each region's attributes to the `mpubase` and `mpuacc` registers as described in the "MPU Region Read and Write Operations" section of this chapter. You must also disable unused regions. When using region size, clear `mpuacc.MASK` to zero. When using limit, set the `mpubase.BASE` to a nonzero value and clear `mpuacc.LIMIT` to zero.

Note: You must enable at least one instruction and one data region, otherwise unpredictable behavior might occur.

To perform a context switch, use a `wrctl` to write a zero to the `PE` field of the `config` register to disable the MPU, define all MPU regions from the new thread's data structure, and then use another `wrctl` to write a one to `config.PE` to enable the MPU.

Define each region using the pair of `wrctl` instructions described in the "MPU Region Read and Write Operations" section of this chapter. Repeat this dual `wrctl` instruction sequence until all desired regions are defined.

Debugger Access

The debugger can access all MPU-related control registers using the normal `wrctl` and `rdctl` instructions. During debugging, the Nios II ignores the MPU, effectively temporarily disabling it.

Working with ECC

Enabling ECC

The ECC is disabled on system reset. Before enabling the ECC, initialize the Nios II RAM blocks to avoid spurious ECC errors.

The Nios II processor executes the `INITI` instruction on each cache line, which initializes the instruction cache RAM. The RAM does not require special initialization because any detected ECC errors are ignored if the line is invalid; the line is invalid after `INITI` instructions initialize the tag RAM.

Nios II processor instructions that write to every register (except register 0) initialize the register file RAM blocks. If shadow register sets are present, this step is performed for all registers in the shadow register set using the `WRPRS` instruction.

Nios II processor instructions that write every TLB RAM location initialize the MMU TLB RAM. This RAM does not require special initialization.

Disabling ECC

Disable ECC in software by writing 0 to `CONFIG.ECCEN`. Software can re-enable ECC without reinitializing the ECC-protected RAMs because the ECC parity bits are written to the RAM blocks even if ECC is disabled.

Handling ECC Errors

ECC error exceptions occur when unrecoverable ECC errors are detected. The software's ability to recover from the ECC error depends on the nature of the error.

Typically, software can recover from an unrecoverable MMU TLB ECC error (2 bit error) because the TLB is a software-managed cache of the operating system page tables stored in the main memory (e.g., SDRAM). Software can invalid the TLB entry, return to the instruction that took the ECC error exception, and execute the TLB's mishandled code to load a TLB entry from the page tables.

In general, software cannot recover from a register file ECC error (2 bit error) because the correct value of a register is not known. If the exception handler reads a register that has a 2 bit ECC error associated with it, another ECC error occurs and an exception handler loop can occur.

Exception handler loops occur when an ECC error exception occurs in the exception handler before it is ready to handle nested exceptions. To minimize the occurrence or exception handler loops, locate the ECC error exception handler code in normal cacheable memory, ensure that all data accesses are to non-cacheable memory, and minimize register reading.

The ECC error signals (`ecc_event_bus`) provide the `EEH` signal for external logic to detect a possible exception handler loop and reset the Nios II processor.

Injecting ECC Errors

This section describes the code sequence for injecting ECC errors for each ECC-protected RAM, assuming the ECC is enabled and interrupts are disabled for the duration of the code sequence.

Instruction Cache Tag RAM

1. Ensure all code up to the JMP instruction is in the same instruction cache line or is located in an ITCM.
2. Use a `FLUSHI` instruction to flush an instruction cache line other than the line containing the executing code.
3. Use a `FLUSHP` instruction to flush the pipeline.
4. Use a `WRCTL` instruction to set `ECCINJ.ICTAG` to `INJS` or `INJD`. This setting causes an ECC error to occur on the start of the next line fill.
5. Use a `JMP` instruction to jump to an instruction address in the flushed line.
6. The ECC error is injected when writing the tag RAM at the start of the line fill.
7. Use a `RDCTL` instruction to ensure that the value of `ECCINJ.ICTAG` is `NOINJ`.
8. The ECC error triggers after the target of the `JMP` instruction.

Instruction Cache Data RAM

1. Ensure all code up to the JMP instruction is in the same instruction cache line or is located in an ITCM.
2. Use a `FLUSHI` instruction to flush an instruction cache line other than the line containing the executing code.
3. Use a `FLUSHP` instruction to flush the pipeline.
4. Use a `WRCTL` instruction to set `ECCINJ.ICDAT` to `INJS` or `INJD`. This setting causes an ECC error to occur on the start of the next line fill.
5. Use a `JMP` instruction to jump to an instruction address in the flushed line.
6. The ECC error is injected when writing the tag RAM at the start of the line fill.
7. Use a `RDCTL` instruction to ensure that the value of `ECCINJ.ICDAT` is `NOINJ`.
8. Execute the target of the `JMP` instruction twice (first to inject the ECC error and second to be triggered by it).

ITCMs

Software running on the Nios II cannot directly inject an ECC error in an `ITCM` because the Nios II only writes `ITCMs` when correcting ECC errors. To inject an ECC in an `ITCM`, the TCM RAM must also be connected to a `DTCM` master. The Nios II provided `DTCM` error injection mechanism (i.e. `ECCINJ` register) is used to inject an error in the TCM RAM as follows:

1. Use a `WRCTL` instruction to set `ECCINJ` so that it will inject ECC errors in the `DTCM` connected to the `ITCM`.
2. Use a `STW` instruction to write the `DTCM`.
3. Use a `RDCTL` instruction to ensure the value of the `ECCINJ` field written by the `WRCTL` is `NOINJ`.
4. Use a `JMP` instruction to jump to an instruction address in the ITCM.
5. The ECC error should be triggered on the target of the `JMP` instruction.

Register File RAM Blocks

1. Use a `WRCTL` instruction to set `ECCINJ.RF` to `INJS` or `INJD` (as desired).
2. Execute any instruction that writes any register except `R0`.
3. Use a `RDCTL` instruction to ensure that the value of `ECCINJ.RF` is `NOINJ`.
4. Use an instruction to read the desired register from rA such as `OR rd, r0, rx` where `rx` is the register written in the previous step. This action triggers the ECC error.
5. Use an instruction to read the desired register from rB such as `OR rd, rx, r0` where `rx` is the register written in the previous step.

Data Cache Tag RAM

1. Use a LOAD instruction from a data address to get the line in the cache. The line should be clean.
2. Use a WRCTL instruction to set ECCINJ.DCTAG to INJS or INJD.
3. Use a STORE instruction from a data address mapped to that line. The STORE instruction should hit in the data cache and write the tag RAM to set the dirty bit.
4. The ECC error is injected when the tag RAM is written.
5. Use a RDCTL instruction to ensure the value of ECCINJ.DCTAG is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
6. Do another LOAD or STORE instruction to the same line.
7. The ECC error should be triggered on this second LOAD/STORE instruction.

Data Cache Data RAM (Clean Line)

1. Use a FLUSHDA instruction to ensure the line isn't in the data cache.
2. Use a LOAD instruction to load a clean data cache line.
3. Use a WRCTL instruction to set ECCINJ.DCDAT field to INJS or INJD.
4. Use a LOAD instruction to an address in the data cache line to inject the error.
5. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
6. Use a LOAD instruction from the same address.
7. The ECC error should be triggered on the LOAD instruction.

Data Cache Data RAM (Dirty Line)

1. Use a LOAD instruction to load a data cache line.
2. Use a WRCTL instruction to set ECCINJ.DCDAT field to INJS or INJD (as desired).
3. Use a STORE instruction to an address in the data cache line.
4. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
5. Either use a LOAD instruction from the same address or trigger a writeback of the dirty line (e.g. FLUSHDA instruction)
6. The ECC error should be triggered on the LOAD instruction unless it is only detected during the writeback of a dirty line. In the writeback of a dirty line case, the ECC error is triggered an undefined number of instructions later.

Data Cache Victim Line Buffer RAM

1. Use a LOAD instruction to load a data cache line.
2. Use a WRCTL instruction to set ECCINJ.DCWB field to INJS or INJD (as desired).
3. Use a STORE instruction to an address in the data cache line.
4. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
5. Either use a LOAD instruction from the same address or trigger a writeback of the dirty line (e.g. FLUSHDA instruction)
6. The ECC error should be triggered on the LOAD instruction unless it is only detected during the writeback of a dirty line. In the writeback of a dirty line case, the ECC error is triggered an undefined number of instructions later.

DTCMs

1. Use a WRCTL instruction to set the ECCINJ.DTCM field to INJS or INJD for the desired DTCM.
2. Use a STW instruction to write an address in the DTCM.
3. Use a RDCTL instruction to ensure the value of the field written by the WRCTL to ECCINJ is NOINJ.
4. Use a LOAD instruction from the same address in the DTCM.
5. The ECC error should be triggered on the LOAD instruction.

MMU TLB RAM

1. Use a WRCTL instruction to set ECCINJ.TLB to INJS or INJD.
2. Use a WRCTL instruction to write a TLB entry. The ECC error will be injected at this time and any associated uTLB entry will be flushed.
3. Use a RDCTL instruction to ensure the value of ECCINJ.TLB is NOINJ.
4. Perform an instruction/data access to cause the hardware to read the TLB entry (copied into uTLB) and the ECC decoder should detect the ECC error at this time. Alternatively, initiate a software read of the TLB (by writing TLBMISC.RD to 1).
5. If a software read was initiated, the TLBMISC.EE field should be set to 1 on any instruction after the WRCTL that triggered the software read.
6. If a hardware read was initiated, the ECC error should be triggered on the first instruction after the hardware read.

Exception Processing

Exception processing is the act of responding to an exception, and then returning, if possible, to the pre-exception execution state.

All Nios II exceptions are precise. Precise exceptions enable the system software to re-execute the instruction, if desired, after handling the exception.

Terminology

Altera Nios II documentation uses the following terminology to discuss exception processing:

*   *Exception*—a transfer of control away from a program's normal flow of execution, caused by an event, either internal or external to the processor, which requires immediate attention.
*   *Interrupt*—an exception caused by an explicit request signal from an external device; also: hardware interrupt.
*   *Interrupt controller*—hardware that interfaces the processor to interrupt request signals from external devices.
*   *Internal interrupt controller*—the nonvectored interrupt controller that is integral to the Nios II processor. The internal interrupt controller is available in all revisions of the Nios II processor.
*   *Vectored interrupt controller* (VIC)—an Altera-provided external interrupt controller.
*   *Exception (interrupt) latency*—The time elapsed between the event that causes the exception (assertion of an interrupt request) and the execution of the first instruction at the handler address.
*   *Exception (interrupt)* response time—The time elapsed between the event that causes the exception (assertion of an interrupt request) and the execution of nonoverhead exception code, that is, specific to the exception type (device).
*   *Global interrupts*—All maskable exceptions on the Nios II processor, including internal interrupts and maskable external interrupts, but not including nonmaskable interrupts.

- *Worst-case latency*—The value of the exception (interrupt) latency, assuming the maximum disabled time or maximum masked time, and assuming that the exception (interrupt) occurs at the beginning of the masked/disabled time.
- *Maximum disabled time*—The maximum amount of continuous time that the system spends with maskable interrupts disabled.
- *Maximum masked time*—The maximum amount of continuous time that the system spends with a single interrupt masked.
- *Shadow register set*—a complete alternate set of Nios II general-purpose registers, which can be used to maintain a separate runtime context for an ISR.

Exception Overview

Each of the Nios II exceptions falls into one of the following categories:

- *Reset exception*—Occurs when the Nios II processor is reset. Control is transferred to the reset address you specify in the Nios II processor IP core setup parameters.
- *Break exception*—Occurs when the JTAG debug module requests control. Control is transferred to the break address you specify in the Nios II processor IP core setup parameters.
- *Interrupt exception*—Occurs when a peripheral device signals a condition requiring service
- *Instruction-related exception*—Occurs when any of several internal conditions occurs, as detailed in the Nios II Exceptions Table. Control is transferred to the exception address you specify in the Nios II processor IP core setup parameters.

The following table columns specify information for the exceptions:

- *Exception*—Gives the name of the exception.
- *Type*—Specifies the exception type.
- *Available*—Specifies when support for that exception is present.
- *Cause*—Specifies the value of the `CAUSE` field of the `exception` register, for exceptions that write the `exception.CAUSE` field.
- *Address*—Specifies the instruction or data address associated with the exception.
- *Vector*—Specifies which exception vector address the processor passes control to when the exception occurs.

Table 3-36: Nios II Exceptions (In Decreasing Priority Order)

Exception	Type	Available	Cause	Address	Vector
Reset	Reset	Always	0		Reset
Hardware break	Break	Always	—		Break
Processor-only reset request	Reset	Always	1		Reset
ECC Data Cache Writeback Error	Instruction-related	ECC and data cache	22		General exception
Internal interrupt	Interrupt	Internal interrupt controller	2	$ea-4^{(15)}$	General exception
External nonmaskable interrupt	Interrupt	External interrupt controller interface	—	$ea-4^{(15)}$	Requested handler address [16]
External maskable interrupt	Interrupt	External interrupt controller interface	2	$ea-4^{(15)}$	Requested handler address [16]

Exception Latency

Exception latency specifies how quickly the system can respond to an exception. Exception latency depends on the type of exception, the software and hardware configuration, and the processor state.

Interrupt Latency

The interrupt controller can mask individual interrupts. Each interrupt can have a different maximum masked time. The worst-case interrupt latency for interrupt i is determined by that interrupt's maximum masked time, or by the maximum disabled time, whichever is greater.

---

[14] It is possible for any instruction fetch to cause this exception.

[15] Refer to the Nios II General-Purpose Registers Table for descriptions of the `ea` and `ba` registers.

[16] For a description of the requested handler address, refer to the Requested Handler Address section of this chapter.

Reset Exceptions

When a processor reset signal is asserted, the Nios II processor performs the following steps:

1. Sets `status.RSIE` to 1, and clears all other fields of the `status` register.
2. Invalidates the instruction cache line associated with the reset vector.
3. Begins executing the reset handler, located at the reset vector.

Note: All noninterrupt exception handlers must run in the normal register set.

Clearing the `status.PIE` field disables maskable interrupts. If the MMU or MPU is present, clearing the `status.U` field forces the processor into supervisor mode.

Note: Nonmaskable interrupts (NMIs) are not affected by `status.PIE`, and can be taken while processing a reset exception.

Invalidating the reset cache line guarantees that instruction fetches for reset code comes from uncached memory.

Aside from the instruction cache line associated with the reset vector, the contents of the cache memories are indeterminate after reset. To ensure cache coherency after reset, the reset handler located at the reset vector must immediately initialize the instruction cache. Next, either the reset handler or a subsequent routine should proceed to initialize the data cache.

The reset state is undefined for all other system components, including but not limited to:

- General-purpose registers, except for `zero` (`r0`) in the normal register set, which is permanently zero.
- Control registers, except for `status`. `status.RSIE` is reset to 1, and the remaining fields are reset to 0.
- Instruction and data memory.
- Cache memory, except for the instruction cache line associated with the reset vector.
- Peripherals. Refer to the appropriate peripheral data sheet or specification for reset conditions.
- Custom instruction logic
- Nios II C-to-hardware (C2H) acceleration compiler logic.

For more information refer to the Nios II Custom Instruction User Guide for reset conditions.

Nios II Custom Instruction User Guide

Break Exceptions

A break is a transfer of control away from a program's normal flow of execution for the purpose of debugging. Software debugging tools can take control of the Nios II processor via the JTAG debug module.

Break processing is the means by which software debugging tools implement debug and diagnostic features, such as breakpoints and watchpoints. Break processing is a type of exception processing, but the break mechanism is independent from general exception processing. A break can occur during exception processing, enabling debug tools to debug exception handlers.

The processor enters the break processing state under either of the following conditions:

- The processor executes the `break` instruction. This is often referred to as a software break.
- The JTAG debug module asserts a hardware break.

Processing a Break

A break causes the processor to take the following steps:

1. Stores the contents of the `status` register to `bstatus`.
2. Clears `status.PIE` to zero, disabling maskable interrupts.

Note: Nonmaskable interrupts (NMIs) are not affected by `status.PIE`, and can be taken while processing a break exception.

1. Writes the address of the instruction following the break to the `ba` register (`r30`) in the normal register set.
2. Clears `status.U` to zero, forcing the processor into supervisor mode, when the system contains an MMU or MPU.
3. Sets `status.EH` to one, indicating the processor is handling an exception, when the system contains an MMU.
4. Copies `status.CRS` to `status.PRS` and then sets `status.CRS` to 0.
5. Transfers execution to the break handler, stored at the break vector specified in the Nios II Processor parameter editor.

Note: All noninterrupt exception handlers, including the break handler, must run in the normal register set.

Understanding Register Usage

The `bstatus` control register and general-purpose registers `bt` (`r25`) and `ba` (`r30`) in the normal register set are reserved for debugging. Code is not prevented from writing to these registers, but debug code might overwrite the values. The break handler can use `bt` (`r25`) to help save additional registers.

Returning From a Break

After processing a break, the break handler releases control of the processor by executing a `bret` instruction. The `bret` instruction restores `status` by copying the contents of `bstatus` and returns program execution to the address in the `ba` register (`r30`) in the normal register set. Aside from `bt` and `ba`, all registers are guaranteed to be returned to their pre-break state after returning from the break handler.

Interrupt Exceptions

A peripheral device can request an interrupt by asserting an interrupt request (IRQ) signal. IRQs interface to the Nios II processor through an interrupt controller. You can configure the Nios II processor with either of the following interrupt controller options:

- The external interrupt controller interface
- The internal interrupt controller

External Interrupt Controller Interface

The Nios II EIC interface enables you to connect the Nios II processor to an external interrupt controller component. The EIC can monitor and prioritize IRQ signals, and determine which interrupt to present to the Nios II processor. An EIC can be software-configurable.

The Nios II processor does not depend on any particular implementation of an EIC. The degree of EIC configurability, and EIC configuration methods, are implementation-specific. This section discusses the EIC interface, and general features of EICs. For usage details, refer to the documentation for the specific EIC in your system.

When an IRQ is asserted, the EIC presents the following information to the Nios II processor:

- The requested handler address (RHA)—Refer to the Requested Handler Address section of this chapter
- The requested interrupt level (RIL)—Refer to the Requested Interrupt Level section of this chapter
- The requested register set (RRS)—Refer to Requested Register Set section of this chapter
- Requested nonmaskable interrupt (RNMI) mode—Refer to the Requested NMI Mode section of this chapter

The Nios II processor EIC interface connects to a single EIC, but an EIC can support a daisy-chained configuration. In a daisy-chained configuration, multiple EICs can monitor and prioritize interrupts. The EIC directly connected to the processor presents the processor with the highest-priority interrupt from all EICs in the daisy chain.

An EIC component can support an arbitrary level of daisy-chaining, potentially allowing the Nios II processor to handle an arbitrary number of prioritized interrupts.

For a typical EIC implementation, refer to the *Vectored Interrupt Controller* chapter in the *Embedded Peripherals IP User Guide*.

- **Embedded Peripherals IP User Guide**
- **Requested NMI Mode** on page 3-45
- **Requested Register Set** on page 3-44
- **Requested Interrupt Level** on page 3-44

Requested Handler Address

The RHA specifies the address of the handler associated with the interrupt. The availability of an RHA for each interrupt allows the Nios II processor to jump directly to the interrupt handler, reducing interrupt latency.

The RHA for each interrupt is typically software-configurable. The method for specifying the RHA is dependent on the specific EIC implementation.

If the Nios II processor is implemented with an MMU, the processor treats handler addresses as virtual addresses.

Requested Interrupt Level

The Nios II processor uses the RIL to decide when to take a maskable interrupt. The interrupt is taken only when the RIL is greater than `status.IL`.

The RIL is ignored for nonmaskable interrupts.

Requested Register Set

If shadow register sets are implemented on the Nios II core, the EIC specifies a register set when it asserts an interrupt request. When it takes the interrupt, the Nios II processor switches to the requested register set. When an interrupt has a dedicated register set, the interrupt handler avoids the overhead of saving registers.

The method of assigning register sets to interrupts depends on the specific EIC implementation. Register set assignments can be software-configurable.

Multiple interrupts can be configured to share a register set. In this case, the interrupt handlers must be written so as to avoid register corruption. For example, one of the following conditions must be true:

- The interrupts cannot pre-empt one another. For example, all interrupts are at the same level.
- Registers are saved in software. For example, each interrupt handler saves its own registers on entry, and restores them on exit.

Typically, the Nios II processor is configured so that when it takes an interrupt, other interrupts in the same register set are disabled. If interrupt preemption within a register set is desired, the interrupt handler can re-enable interrupts in its register set.

By default, the Nios II processor disables maskable interrupts when it takes an interrupt request. To enable nested interrupts, system software or the ISR itself must re-enable interrupts after the interrupt is taken.

Requested NMI Mode

Any interrupt can be nonmaskable, depending on the configuration of the EIC. An NMI typically signals a critical system event requiring immediate handling, to ensure either system stability or real-time performance.

`status.IL` and RIL are ignored for nonmaskable interrupts.

Shadow Register Sets

Although shadow register sets can be implemented independently of the EIC interface, typically the two features are used together. Combining shadow register sets with an appropriate EIC, you can minimize or eliminate the context switch overhead for critical interrupts.

For the best interrupt performance, assign a dedicated register set to each of the most time-critical interrupts. Less-critical interrupts can share register sets, provided the ISRs are protected from register corruption as noted in the Requested Register Set section of this chapter.

The method for mapping interrupts to register sets is specific to the particular EIC implementation.

Related Information

Internal Interrupt Controller

When the internal interrupt controller is implemented, a peripheral device can request a hardware interrupt by asserting one of the Nios II processor's 32 interrupt-request inputs, `irq0` through `irq31`. A hardware interrupt is generated if and only if all three of these conditions are true:

- The `PIE` bit of the `status` control register is one.
- An interrupt-request input, `irqn`, is asserted.
- The corresponding bit n of the `ienable` control register is one.

Upon hardware interrupt, the processor clears the `PIE` bit to zero, disabling further interrupts, and performs the other steps outlined in the "Exception Processing Flow" section of this chapter.

The value of the `ipending` control register shows which interrupt requests (IRQ) are pending. By peripheral design, an IRQ bit is guaranteed to remain asserted until the processor explicitly responds to the peripheral.

Note: Although shadow register sets can be implemented in any Nios II/f processor, the internal interrupt controller does not have features to take advantage of it as external interrupt controllers do.

Figure 3-2: Relationship Between ienable, ipending, PIE and Hardware Interrupts
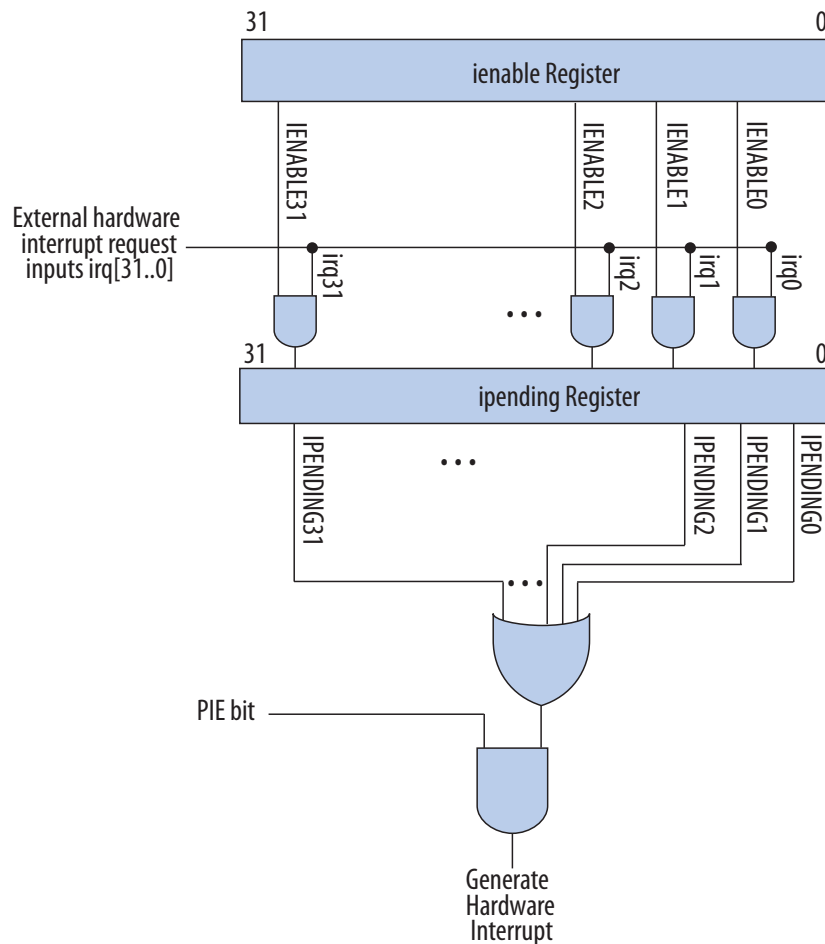

Related Information

Exception Processing Flow on page 3-51

Instruction-Related Exceptions

Instruction-related exceptions occur during execution of Nios II instructions. When they occur, the processor perform the steps outlined in the "Exception Processing Flow" section of this chapter.

The Nios II processor generates the following instruction-related exceptions:

- Trap instruction
- Break instruction
- Unimplemented instruction
- Illegal instruction
- Supervisor-only instruction
- Supervisor-only instruction address
- Supervisor-only data address
- Misaligned data address
- Misaligned destination address

- Division error
- Fast TLB miss
- Double TLB miss
- TLB permission violation
- MPU region violation

Note: All noninterrupt exception handlers must run in the normal register set.

Related Information
Exception Processing Flow on page 3-51

Trap Instruction

When a program issues the `trap` instruction, the processor generates a software trap exception. A program typically issues a software trap when the program requires servicing by the operating system. The general exception handler for the operating system determines the reason for the trap and responds appropriately.

Break Instruction

The break instruction is treated as a break exception. For more information, refer to the "Break Exceptions" section of this chapter.

Related Information
Break Exceptions on page 3-42

Unimplemented Instruction

When the processor issues a valid instruction that is not implemented in hardware, an unimplemented instruction exception is generated. The general exception handler determines which instruction generated the exception. If the instruction is not implemented in hardware, control is passed to an exception routine that might choose to emulate the instruction in software.

For more information, refer to the "Potential Unimplemented Instructions" section of this chapter.

Related Information
Potential Unimplemented Instructions on page 3-67

Illegal Instruction

Illegal instructions are instructions with an undefined opcode or opcode-extension field. The Nios II processor can check for illegal instructions and generate an exception when an illegal instruction is encountered. Illegal instruction checking is always on regardless of MMU or MPU settings.

For information about controlling this option, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

When the processor issues an instruction with an undefined opcode or opcode-extension field, and illegal instruction exception checking is turned on, an illegal instruction exception is generated.

Refer to the OP Encodings and OPX Encodings for R-Type Instructions tables in the *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook* to see the unused opcodes and opcode extensions.

Note: All undefined opcodes are reserved. The processor does occasionally use some undefined encodings internally. Executing one of these undefined opcodes does not trigger an illegal instruction exception.

Refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook* for information about each specific Nios II core.

- **Nios II Core Implementation Details** on page 5-1

Supervisor-Only Instruction

When your system contains an MMU or MPU and the processor is in user mode (`status.U = 1`), executing a supervisor-only instruction results in a supervisor-only instruction exception. The supervisor-only instructions are `initd`, `initi`, `eret`, `bret`, `rdctl`, and `wrctl`.

This exception is implemented only in Nios II processors configured to use supervisor mode and user mode. Refer to the "Operating Modes" section of this chapter for more information.

Related Information

Operating Modes on page 3-1

Supervisor-Only Instruction Address

When your system contains an MMU and the processor is in user mode (`status.U = 1`), attempts to access a supervisor-only instruction address result in a supervisor-only instruction address exception. Any instruction fetch can cause this exception. For definitions of supervisor-only address ranges, refer to the Virtual Memory Partitions Table.

This exception is implemented only in Nios II processors that include the MMU.

Related Information

Virtual Memory Address Space on page 3-4

Supervisor-Only Data Address

When your system contains an MMU and the processor is in user mode (`status.U = 1`), any attempt to access a supervisor-only data address results in a supervisor-only data address exception. Instructions that can cause a supervisor-only data address exception are all loads, all stores, and `flushda`.

This exception is implemented only in Nios II processors that include the MMU.

Misaligned Data Address

The Nios II processor can check for misaligned data addresses of load and store instructions and generate an exception when a misaligned data address is encountered. When your system contains an MMU or MPU, misaligned data address checking is always on. When no MMU or MPU is present, you have the option to have the processor check for misaligned data addresses.

For information about controlling this option, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook.*

A data address is considered misaligned if the byte address is not a multiple of the width of the load or store instruction data width (four bytes for word, two bytes for half-word). Byte load and store instructions are always aligned so never take a misaligned address exception.

Related Information

Programming Model on page 3-1

Misaligned Destination Address

The Nios II processor can check for misaligned destination addresses of the `callr`, `jmp`, `ret`, `eret`, `bret`, and all branch instructions and generate an exception when a misaligned destination address is encountered. When your system contains an MMU or MPU, misaligned destination address checking is always on. When no MMU or MPU is present, you have the option to have the processor check for misaligned destination addresses.

For information about controlling this option, refer to the *Instantiating the Nios II Processor* chapter of the *Nios II Processor Reference Handbook*.

A destination address is considered misaligned if the target byte address of the instruction is not a multiple of four.

Related Information

Programming Model on page 3-1

Division Error

The Nios II processor can check for division errors and generate an exception when a division error is encountered.

The division error exception detects divide instructions that produce a quotient that can't be represented. The two cases are divide by zero and a signed division that divides the largest negative number -2147483648 (0x80000000) by -1 (0xffffffff). Division error detection is only available if divide instructions are supported by hardware.

Related Information

Programming Model on page 3-1

Fast TLB Miss

Fast TLB miss exceptions are implemented only in Nios II processors that include the MMU. The MMU has a special exception vector (fast TLB miss), specified with the Nios II Processor parameter editor in Qsys, specifically to handle TLB miss exceptions quickly. Whenever the processor cannot find a TLB entry matching the VPN (optionally extended by a process identifier), the result is a TLB miss exception. At the time of the exception, the processor first checks `status.EH`. When `status.EH` = 0, no other exception is already in process, so the processor considers the TLB miss a fast TLB miss, sets `status.EH` to one, and transfers control to the fast TLB miss exception handler (rather than to the general exception handler).

There are two kinds of fast TLB miss exceptions:

- Fast TLB miss (instruction)—Any instruction fetch can cause this exception.
- Fast TLB miss (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The fast TLB miss exception handler can inspect the `tlbmisc.D` field to determine which kind of fast TLB miss exception occurred.

Double TLB Miss

Double TLB miss exceptions are implemented only in Nios II processors that include the MMU. When a TLB miss exception occurs while software is currently processing an exception (that is, when `status.EH` = 1), a double TLB miss exception is generated. Specifically, whenever the processor cannot find a TLB entry matching the VPN (optionally extended by a process identifier) and `status.EH` = 1, the result is a double TLB miss exception. The most common scenario is that a double TLB miss exception occurs during processing of a fast TLB miss exception. The processor preserves register values from the original

exception and transfers control to the general exception handler which processes the newly-generated exception.

There are two kinds of double TLB miss exceptions:

- Double TLB miss (instruction)—Any instruction fetch can cause this exception.
- Double TLB miss (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The general exception handler can inspect either the `exception.CAUSE` or `tlbmisc.D` field to determine which kind of double TLB miss exception occurred.

TLB Permission Violation

TLB permission violation exceptions are implemented only in Nios II processors that include the MMU. When a TLB entry is found matching the VPN (optionally extended by a process identifier), but the permissions do not allow the access to complete, a TLB permission violation exception is generated.

There are three kinds of TLB permission violation exceptions:

- TLB permission violation (execute)—Any instruction fetch can cause this exception.
- TLB permission violation (read)—Any load instruction can cause this exception.
- TLB permission violation (write)—Any store instruction can cause this exception.

The general exception handler can inspect the `exception.CAUSE` field to determine which permissions were violated.

Note: The data cache management instructions (`initd`, `initda`, `flushd`, and `flushda`) ignore the TLB permissions and do not generate TLB permission violation exceptions.

MPU Region Violation

MPU region violation exceptions are implemented only in Nios II processors that include the MPU. An MPU region violation exception is generated under any of the following conditions:

- An instruction fetch or data address matched a region but the permissions for that region did not allow the action to complete.
- An instruction fetch or data address did not match any region.

The general exception handler reads the MPU region attributes to determine if the address did not match any region or which permissions were violated.

There are two kinds of MPU region violation exceptions:

- MPU region violation (instruction)—Any instruction fetch can cause this exception.
- MPU region violation (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The general exception handler can inspect the `exception.CAUSE` field to determine which kind of MPU region violation exception occurred.

Other Exceptions

The preceding sections describe all of the exception types defined by the Nios II architecture at the time of publishing. However, some processor implementations might generate exceptions that do not fall into the categories listed in the preceding sections. Therefore, a robust exception handler must provide a safe response (such as issuing a warning) in the event that it cannot identify the cause of an exception.

Exception Processing Flow

Except for the break exception (refer to the Processing a Break section of this chapter), this section describes how the processor responds to exceptions, including interrupts and instruction-related exceptions.

Related Information

- **Exception Handling**
  For details about writing programs to take advantage of exception and interrupt handling, refer to the Exception Handling chapter of the Nios II Software Developer's Handbook.
- **Processing a Break** on page 3-42

Processing General Exceptions

The general exception handler is a routine that determines the cause of each exception (including the double TLB miss exception), and then dispatches an exception routine to respond to the exception. The address of the general exception handler, specified with the Nios II Processor parameter editor in Qsys, is called the exception vector in the Nios II Processor parameter editor. At run time this address is fixed, and software cannot modify it. Programmers do not directly access exception vectors, and can write programs without awareness of the address.

Note: If the EIC interface is present, the general exception handler processes only noninterrupt exceptions.

The fast TLB miss exception handler only handles the fast TLB miss exception. It is built for speed to process TLB misses quickly. The fast TLB miss exception handler address, specified with the Nios II Processor parameter editor in Qsys, is called the fast TLB miss exception vector in the Nios II Processor parameter editor.

Exception Flow with the EIC Interface

If the EIC interface is present, interrupt processing differs markedly from noninterrupt exception processing. The EIC interface provides the following information to the Nios II processor for each interrupt request:

- RHA—The requested handler address for the interrupt handler assigned to the requested interrupt.
- RRS—The requested register set to be used when the interrupt handler executes. If shadow register sets are not implemented, RRS must always be 0.
- RIL—The requested interrupt level specifies the priority of the interrupt.
- RNMI—The requested NMI flag specifies whether to treat the interrupt as nonmaskable.

  For further information about the RHA, RRS, RIL and RNMI, refer to "The Nios II/f Core" in the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

When the EIC interface presents an interrupt to the Nios II processor, the processor uses several criteria, as follows, to determine whether to take the interrupt:

- Nonmaskable interrupts—The processor takes any NMI as long as it is not processing a previous NMI.
- Maskable interrupts—The processor takes a maskable interrupt if maskable interrupts are enabled, and if the requested interrupt level is higher than that of the interrupt currently being processed (if any). However, if shadow register sets are implemented, the processor takes the interrupt only if the interrupt requests a register set different from the current register set, or if the register set interrupt enable flag (status.RSIE) is set.

Table 3-37: Conditions Required to Take External Interrupt

RNMI == 1		RNMI == 0					
			status.PIE == 1				
				RIL > status.IL			
				Processor Has Shadow Register Sets			
status.NMI == 0	status.NMI == 1	status.PIE == 0	RIL <= status.IL	RRS == status.CRS		RRS != status.CRS	No Shadow Register Sets
				status.RSIE == 0	status.RSIE == 1		
Yes	No	No	No	No [17]	Yes	Yes	Yes

The Nios II processor supports fast nested interrupts with shadow register sets, as described in the "Shadow Register Set" section of this chapter.

Keeping status.PIE set allows higher level interrupts to be taken immediate, without requiring the interrupt handler to set status.PIE to 1.

The processor disables maskable interrupts when taking an exception, just as it does without shadow register sets. An individual interrupt handler can re-enable interrupts by setting status.PIE to 1, if desired.

Related Information

- **Shadow Register Sets** on page 3-45
- **Nios II Core Implementation Details** on page 5-1

Exception Flow with the Internal Interrupt Controller

A general exception handler determines which of the pending interrupts has the highest priority, and then transfers control to the appropriate ISR. The ISR stops the interrupt from being visible (either by clearing it at the source or masking it using ienable) before returning and/or before re-enabling PIE. The ISR also saves estatus and ea (r29) before re-enabling PIE.

Interrupts can be re-enabled by writing one to the PIE bit, thereby allowing the current ISR to be interrupted. Typically, the exception routine adjusts ienable so that IRQs of equal or lower priority are disabled before re-enabling interrupts.

Refer to "Handling Nested Exceptions" for more information.

---

[17] Nested interrupts using the same register set are allowed only if system software has explicitly permitted them by setting status.RSIE. This restriction ensures that such interrupts are taken only if the handler is coded to save the register context.

Related Information

Exceptions and Processor Status

The Nios II Processor Status After Taking Exception Table lists all changes to the Nios II processor state as a result of nonbreak exception processing actions performed by hardware. For systems with an MMU, `status.EH` indicates whether or not exception processing is already in progress. When `status.EH = 1`, exception processing is already in progress and the states of the exception registers are preserved to retain the original exception states.

Table 3-38: Nios II Processor Status After Taking Exception

Processor Status Register or Field	System Status Before Taking Exception							
	External Interrupt Asserted [18]				Internal Interrupt Asserted or Noninterrupt Exception			
	status.EH==1 [33]		status.EH==0		status.EH==1	status.EH==0		
							No TLB Miss	
	RRS==0 [34]	RRS!=0	RRS==0	RRS!=0		TLB Miss [35]	TLB Permission Violation [35]	No TLB Permission Violation
`pteaddr.VPN` [19]	No change					VPN [20]		No change
`status.PRS` [34]	No change		`status.CRS` [34] [36]		No change			
`pc`	RHA				General exception vector [21]	Fast TLB exception vector [22]	General exception vector [34]	
`sstatus` [23][37]	No change			`status` [36] [24]	No change			
`estatus` [37]	No change		`status` [36]	No change			`status` [36]	
`ea`	No change		return address [25]		No change		return address	
`tlbmisc.D` [33]	No change					[26]		
`tlbmisc.DBL` [33]	No change					[27]		
`tlbmisc.PERM` [33]	No change					[28]		
`tlbmisc.BAD` [33]	No change					[29]		
`status.PIE`	No change				0 [30]			

---

[18] If the Nios II processor does not have an EIC interface, external interrupts do not occur.
[19] If the Nios II processor does not have an MMU, this register is not implemented.
[20] The VPN of the address triggering the exception
[21] Invokes the general exception handler
[22] Invokes the fast TLB miss exception handler
[23] If the Nios II processor does not have shadow register sets, this register is not implemented.
[24] `sstatus.SRS` is set to 1 if RRS is not equal to `status.CRS`.
[25] The address following the instruction being executed when the exception occurs
[26] Set to 1 on a data access exception, set to 0 otherwise
[27] Set to 1 on a double TLB miss, set to 0 otherwise
[28] Set to 1 on a TLB permission violation, set to 0 otherwise
[29] Set to 1 on a bad virtual address exception, set to 0 otherwise

Processor Status Register or Field	System Status Before Taking Exception							
	External Interrupt Asserted (18)				Internal Interrupt Asserted or Noninterrupt Exception			
	status.EH==1 (33)		status.EH==0		status.EH==1	status.EH==0		
							No TLB Miss	
	RRS==0 (34)	RRS!=0	RRS==0	RRS!=0		TLB Miss (35)	TLB Permission Violation (35)	No TLB Permission Violation
status.EH(33)	No change				1 (31)			
status.IH (39)	1				No change			
status.NMI (39)	RNMI				No change			
status.IL (39)	RIL				No change			
status.RSIE (34)(39)	0				No change			
status.CRS (34)	RRS				No change			
status.U (33)	0 (32)							

Determining the Cause of Interrupt and Instruction-Related Exceptions

The general exception handler must determine the cause of each exception and then transfer control to an appropriate exception routine.

Nios II/f Exception Processing

The CAUSE field of the exception register contains a code for the highest-priority exception occurring at the time. The BADDR field of the badaddr register contains the byte instruction address or data address for certain exceptions.

Refer to the Nios II Exceptions table for more information in the Exception Overview section.

Note: External interrupts do not set exception.CAUSE.

To determine the cause of an exception, simply read the cause of the exception from exception.CAUSE and then transfer control to the appropriate exception routine.

---

(18) If the Nios II processor does not have an EIC interface, external interrupts do not occur.
(30) Disables exceptions and nonmaskable interrupts
(31) If the MMU is implemented, indicates that the processor is handling an exception.
(32) Puts the processor in supervisor mode.
(33) If the Nios II processor does not have an MMU, this field is not implemented. Its value is always 0, and the processor behaves accordingly.
(34) If the Nios II processor does not have shadow register sets, this field is not implemented. Its value is always 0, and the processor behaves accordingly.
(35) If the Nios II processor does not have an MMU, TLB-related exceptions do not occur.
(36) The pre-exception value
(37) Saves the processor's pre-exception status
(38) If the MMU is implemented, indicates that the processor is handling an exception.
(39) If the Nios II processor does not have an EIC interface, this field is not implemented.

Nios II/e Exception Processing

Example 3-3: Determining Exception Cause for Nios II/e Exception Processing

```
/* With an internal interrupt controller, check for interrupt
   exceptions. With an external interrupt controller, ipending is
   always 0, and this check can be omitted. */
if (estatus.PIE == 1 and ipending != 0) {
   handle interrupt

/* Decode exception from instruction */
/* Note: Because the exception register is included with the MMU and */
/* MPU, you never need to determine MMU or MPU exceptions by decoding */
} else {
   decode instruction at $ea-4
   if (instruction is trap)
      handle trap exception
   else if (instruction is load or store)
      handle misaligned data address exception
   else if (instruction is branch, bret, callr, eret, jmp, or ret)
      handle misaligned destination address exception
   else if (instruction is unimplemented)
      handle unimplemented instruction exception
   else if (instruction is illegal)
      handle illegal instruction exception
   else if (instruction is divide) {
      if (denominator == 0)
         handle division error exception
      else if (instruction is signed divide and numerator == 0x80000000
                                      and denominator == 0xffffffff)
         handle division error exception
   }
}

/* Not any known exception */
} else {
   handle unknown exception (If internal interrupt controller
      is implemented, could be spurious interrupt)
}
}
```

Handling Nested Exceptions

The Nios II processor supports several types of nested exceptions, depending on which optional features are implemented. Nested exceptions can occur under the following circumstances:

- An exception handler enables maskable interrupts
- An EIC is present, and an NMI occurs
- An EIC is present, and the processor is configured to keep maskable interrupts enabled when taking an interrupt
- An exception handler triggers an instruction-related exception

   For details about when the Nios II processor takes exceptions, refer to "Exception Processing Flow" on page 3–44.

For details about unimplemented instructions, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook.*

For details about MMU and MPU exceptions, refer to the Instruction-Related Exceptions section of this chapter.

A system can be designed to eliminate the possibility of nested exceptions. However, if nested exceptions are possible, the exception handlers must be carefully written to prevent each handler from corrupting the context in which a pre-empted handler runs.

If an exception handler issues a `trap` instruction, an optional instruction, or an instruction which could generate an MMU or MPU exception, it must save and restore the contents of the `estatus` and `ea` registers.

Related Information

- **Exception Processing Flow** on page 3-51
- **Instruction-Related Exceptions** on page 3-46
- **Processor Architecture** on page 2-1

Nested Exceptions with the Internal Interrupt Controller

You can enable nested exceptions in each exception handler on a case-by-case basis. If you want to allow a given exception handler to be pre-empted, set `status.PIE` to 1 near the beginning of the handler. Enabling maskable interrupts early in the handler minimizes the worst-case latency of any nested exceptions.

Note: Ensure that all pre-empting handlers preserve the register contents.

Nested Exceptions with an External Interrupt Controller

With an EIC, handling of nested interrupts is more sophisticated than with the internal interrupt controller. Handling of noninterrupt exceptions, however, is the same.

When individual external interrupts have dedicated shadow register sets, the Nios II processor supports fast interrupt handling with no overhead for saving register contents. To take full advantage of fast interrupt handling, system software must set up certain conditions. With the following conditions satisfied, ISRs need not save and restore register contents on entry and exit:

- Automatic nested interrupts are enabled.
- Each interrupt is assigned to a dedicated shadow register set.
- All interrupts with the same RIL are assigned to dedicated shadow register sets.
- Multiple interrupts with different RILs can be assigned to a single shadow register set. However, with multiple register sets, you must not allow the RILs assigned to one shadow register set to overlap the RILs assigned to another register set.

  The following tables demonstrate the validity of register set assignments when preemption within a register set is enabled.

Table 3-39: Example of Illegal RIL Assignment

RIL	Register Set 1	Register Set 2
1	IRQ0	
2	IRQ1	
3		IRQ2
4	IRQ3	
5		IRQ4

RIL	Register Set 1	Register Set 2
6		IRQ5
7		IRQ6

Table 3-40: Example of Legal RIL Assignment

RIL	Register Set 1	Register Set 2
1	IRQ0	
2	IRQ1	
3	IRQ3	
4		IRQ2
5		IRQ4
6		IRQ5
7		IRQ6

Note: Noninterrupt exception handlers must always save and restore the register contents, because they run in the normal register set.

Multiple interrupts can share a register set, with some loss of performance. There are two techniques for sharing register sets:

- Set `status.RSIE` to 0. When an ISR is running in a given register set, the processor does not take any maskable interrupt assigned to the same register set. Such interrupts must wait for the running ISR to complete, regardless of their interrupt level.

Note: This technique can result in a priority inversion.

- Ensure that each ISR saves and restores registers on entry and exit, and set `status.RSIE` to 1 after registers are saved. When an ISR is running in a given register set, the processor takes an interrupt in the same register set if it has a higher interrupt level.

The Nios II processor disables interrupts when taking a maskable interrupt (nonmaskable interrupts always disable maskable interrupts). Individual ISRs can re-enable nested interrupts by setting `status.PIE` to 1, as described in the Nested "Exceptions with Internal Interrupt Controller" section of this chapter.

Related Information

Handling Nonmaskable Interrupts

Writing an NMI handler involves the same basic techniques as writing any other interrupt handler. However, nonmaskable interrupts always preempt maskable interrupts, and cannot be preempted. This knowledge can simplify handler design in some ways, but it means that an NMI handler can have a significant impact on overall interrupt latency. For the best system performance, perform the absolute minimum of processing in your NMI handlers, and defer less-critical processing to maskable interrupt handlers or foreground software.

NMIs leave intact the processor state associated with maskable interrupts and other exceptions, as well as normal, nonexception processing, when each NMI is assigned to a dedicated shadow register set. Therefore, NMIs can be handled transparently.

Note: If not assigned to a dedicated shadow register set, an NMI can overwrite the processor status associated with exception processing, making it impossible to return to the interrupted exception.

Note: Do not set `status.PIE` in a nonmaskable ISR. If `status.PIE` is set, a maskable interrupt can pre-empt an NMI, and the processor exits NMI mode. It cannot be returned to NMI mode until the next nonmaskable interrupt.

Masking and Disabling Exceptions

The Nios II processor provides several methods for temporarily turning off some or all exceptions from software. The available methods depend on the hardware configuration. This section discusses all potentially available methods.

Disabling Maskable Interrupts

Software can disable and enable maskable interrupts with the `status.PIE` bit. When `PIE = 0`, maskable interrupts are ignored. When `PIE = 1`, internal and maskable external interrupts can be taken, depending on the status of the interrupt controller.

Masking Interrupts with an External Interrupt Controller

Typical EIC implementations allow system software to mask individual interrupts. The method of masking individual interrupts is implementation-specific.

The `status.IL` field controls what level of external maskable interrupts can be serviced. The processor services a maskable interrupt only if its requested interrupt level is greater than `status.IL`.

An ISR can make run-time adjustments to interrupt nesting by manipulating `status.IL`. For example, if an ISR is running at level 5, to temporarily allow pre-emption by another level 5 interrupt, it can set `status.IL` to 4.

To enable all external interrupts, set `status.IL` to 0. To disable all external interrupts, set `status.IL` to 63.

Masking Interrupts with the Internal Interrupt Controller

The `ienable` register controls the handling of internal hardware interrupts. Each bit of the `ienable` register corresponds to one of the interrupt inputs, `irq0` through `irq31`. A value of one in bit n means that the corresponding `irqn` interrupt is enabled; a bit value of zero means that the corresponding interrupt is disabled.

Refer to the "Exception Processing" section of this chapter for more information.

An ISR can adjust `ienable` so that IRQs of equal or lower priority are disabled. Refer to the "Handling Nested Exceptions" section of this chapter for more information.

- **Exception Processing** on page 3-38

Returning From Interrupt and Instruction-Related Exceptions

The `eret` instruction is used to resume execution at the pre-exception address.

You must ensure that when an exception handler modifies registers, they are restored when it returns. This can be taken care of in either of the following ways:

- In the case of ISRs, if the EIC interface and shadow register sets are implemented, and the ISR has a dedicated register set, no software action is required. The Nios II processor returns to the previous register set when it executes `eret`, which restores the register contents.
- For details, refer to the "Nested Exceptions with an External Interrupt Controller" section of this chapter.
- In the case of noninterrupt exceptions, for ISRs in a system with the internal interrupt controller, and for ISRs without a dedicated shadow register set, the exception handler must save registers on entry and restore them on exit. Saving the register contents on the stack is a typical, re-entrant implementation.

Note: It is not necessary to save and restore the exception temporary (`et` or `r24`) register.

When executing the `eret` instruction, the processor performs the following tasks:

1. Restores the previous contents of `status` as follows:

   - If `status.CRS` is 0, copies `estatus` to `status`
   - If `status.CRS` is nonzero, copies `sstatus` to `status`

2. Transfers program execution to the address in the `ea` register (`r29`) in the register set specified by the original value of `status.CRS`.

Note: The `eret` instruction can cause the processor to exit NMI mode. However, it cannot make the processor enter NMI mode. In other words, if `status.NMI` is 0 and `estatus.NMI` (or `sstatus.NMI`) is 1, after an `eret`, `status.NMI` is still 0. This restriction prevents the processor from accidentally entering NMI mode.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software, including ISRs, is built with the version of the GCC compiler included in Nios II EDS version 9.0 or later. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

[**Nested Exceptions with the Internal Interrupt Controller**](#) on page 3-56

Return Address Considerations

The return address requires some consideration when returning from exception processing routines. After an exception occurs, `ea` contains the address of the instruction following the point where the exception occurred.

When returning from instruction-related exceptions, execution must resume from the instruction following the instruction where the exception occurred. Therefore, `ea` contains the correct return address.

On the other hand, hardware interrupt exceptions must resume execution from the interrupted instruction itself. In this case, the exception handler must subtract 4 from `ea` to point to the interrupted instruction.

Memory and Peripheral Access

Nios II addresses are 32 bits, allowing access up to a 4-gigabyte address space. The MMU supports the full 32-bit physical address. Bit 31 bypass is optional, you can access full 32-bit addressing without the MMU.

For details, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Peripherals, data memory, and program memory are mapped into the same address space. The locations of memory and peripherals within the address space are determined at system generation time. Reading or writing to an address that does not map to a memory or peripheral produces an undefined result.

The processor's data bus is 32 bits wide. Instructions are available to read and write byte, half-word (16-bit), or word (32-bit) data.

The Nios II architecture uses little-endian byte ordering. For data wider than 8 bits stored in memory, the more-significant bits are located in higher addresses.

The Nios II architecture supports register and immediate addressing.

Related Information
Nios II Core Implementation Details on page 5-1

Cache Memory

The Nios II architecture and instruction set accommodate the presence of data cache and instruction cache memories. Cache management is implemented in software by using cache management instructions. Instructions are provided to initialize the cache, flush the caches whenever necessary, and to bypass the data cache to properly access memory-mapped peripherals.

The Nios II architecture provides the following mechanisms to bypass the cache:

- When no MMU is present, bit 31 of the address is reserved for the optial bit-31 cache bypass. With bit-31 cache bypass, the address space of processor cores is 2 GB, and the high bit of the address controls the caching of data memory accesses.
- When the MMU is present, cacheability is controlled by the MMU, and bit 31 functions as a normal address bit. For details, refer to the Address Space and Memory Partitions section , and the TLB Organization section of this chapter.
- Cache bypass instructions, such as `ldwio` and `stwio`.

Refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook* for details of which processor cores implement bit-31 cache bypass.

Refer to *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook* for details of the cache bypass instructions.

Code written for a processor core with cache memory behaves correctly on a processor core without cache memory. The reverse is not true. If it is necessary for a program to work properly on multiple Nios II processor core implementations, the program must behave as if the instruction and data caches exist. In systems without cache memory, the cache management instructions perform no operation, and their effects are benign.

For a complete discussion of cache management, refer to the*Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Some consideration is necessary to ensure cache coherency after processor reset. Refer to "Reset Exceptions" section of this chapter for more information.

For information about the cache architecture and the memory hierarchy refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*.

Virtual Address Aliasing

A virtual address alias occurs when two virtual addresses map to the same physical address. When an MMU and caches are present and the caches are larger than a page (4 KB), the operating system must prevent illegal virtual address aliases. Because the caches are virtually-indexed and physically-tagged, a portion of the virtual address is used to select the cache line. If the cache is 4 KB or less in size, the portion of the virtual address used to select the cache line fits with bits 11:0 of the virtual address which have the same value as bits 11:0 of the physical address (they are untranslated bits of the page offset). However, if the cache is larger than 4 KB, bits beyond the page offset (bits 12 and up) are used to select the cache line and these bits are allowed to be different than the corresponding physical address.

For example, in a 64-KB direct-mapped cache with a 16-byte line, bits 15:4 are used to select the line. Assume that virtual address 0x1000 is mapped to physical address 0xF000 and virtual address 0x2000 is also mapped to physical address 0xF000. This is an illegal virtual address alias because accesses to virtual address 0x1000 use line 0x1 and accesses to virtual address 0x2000 use line 0x2 even though they map to the same physical address. This results in two copies of the same physical address in the cache. With an n-byte direct-mapped cache, there could be n/4096 copies of the same physical address in the cache if illegal virtual address aliases are not prevented. The bits of the virtual address that are used to select the line and are translated bits (bits 12 and up) are known as the color of the address. An operating system avoids illegal virtual address aliases by ensuring that if multiple virtual addresses map the same physical address, the virtual addresses have the same color. Note though, the color of the virtual addresses does not need to be the same as the color as the physical address because the cache tag contains all the bits of the PFN.

Instruction Set Categories

This section introduces the Nios II instructions categorized by type of operation performed.

Data Transfer Instructions

The Nios II architecture is a load-store architecture. Load and store instructions handle all data movement between registers, memory, and peripherals. Memories and peripherals share a common address space. Some Nios II processor cores use memory caching and/or write buffering to improve memory bandwidth. The architecture provides instructions for both cached and uncached accesses.

Table 3-41: Wide Data Transfer Instructions

Instruction	Description
ldw stw	The ldw and stw instructions load and store 32-bit data words from/to memory. The effective address is the sum of a register's contents and a signed immediate value contained in the instruction. Memory transfers can be cached or buffered to improve program performance. This caching and buffering might cause memory cycles to occur out of order, and caching might suppress some cycles entirely. Data transfers for I/O peripherals should use ldwio and stwio.

Instruc-tion	Description
ldwio stwio	ldwio and stwio instructions load and store 32-bit data words from/to peripherals without caching and buffering. Access cycles for ldwio and stwio instructions are guaranteed to occur in instruction order and are never suppressed.

Table 3-42: Narrow Data Transfer Instructions

Instruction	Description
ldb ldbu stb ldh ldhu sth	ldb, ldbu, ldh and ldhu load a byte or half-word from memory to a register. ldb and ldh sign-extend the value to 32 bits, and ldbu and ldhu zero-extend the value to 32 bits. stb and sth store byte and half-word values, respectively. Memory accesses can be cached or buffered to improve performance. To transfer data to I/O peripherals, use the io versions of the instructions, described in the following table cell.
ldbio ldbuio stbio ldhio ldhuio sthio	These operations load/store byte and half-word data from/to peripherals without caching or buffering.

Arithmetic and Logical Instructions

Logical instructions support and, or, xor, and nor operations. Arithmetic instructions support addition, subtraction, multiplication, and division operations.

Table 3-43: Arithmetic and Logical Instructions

Instruction	Description
and or xor nor	These are the standard 32-bit logical operations. These operations take two register values and combine them bit-wise to form a result for a third register.
andi ori xori	These operations are immediate versions of the and, or, and xor instructions. The 16-bit immediate value is zero-extended to 32 bits, and then combined with a register value to form the result.
andhi orhi xorhi	In these versions of and, or, and xor, the 16-bit immediate value is shifted logically left by 16 bits to form a 32-bit operand. Zeroes are shifted in from the right.
add sub mul div divu	These are the standard 32-bit arithmetic operations. These operations take two registers as input and store the result in a third register.

Instruction	Description
addi subi muli	These instructions are immediate versions of the `add`, `sub`, and `mul` instructions. The instruction word includes a 16-bit signed value.
mulxss mulxuu	These instructions provide access to the upper 32 bits of a 32x32 multiplication operation. Choose the appropriate instruction depending on whether the operands should be treated as signed or unsigned values. It is not necessary to precede these instructions with a `mul`.
mulxsu	This instruction is used in computing a 128-bit result of a 64x64 signed multiplication.

Move Instructions

These instructions provide move operations to copy the value of a register or an immediate value to another register.

Table 3-44: Move Instructions

Instruction	Description
mov movhi movi movui movia	`mov` copies the value of one register to another register. `movi` moves a 16-bit signed immediate value to a register, and sign-extends the value to 32 bits. `movui` and `movhi` move a 16-bit immediate value into the lower or upper 16-bits of a register, inserting zeros in the remaining bit positions. Use `movia` to load a register with an address.

Comparison Instructions

The Nios II architecture supports a number of comparison instructions. All of these compare two registers or a register and an immediate value, and write either one (if true) or zero to the result register. These instructions perform all the equality and relational operators of the C programming language.

Table 3-45: Comparison Instructions

Instruction	Description
cmpeq	==
cmpne	!=
cmpge	signed >=
cmpgeu	unsigned >=
cmpgt	signed >
cmpgtu	unsigned >
cmple	unsigned <=
cmpleu	unsigned <=
cmplt	signed <
cmpltu	unsigned <

Instruction	Description
cmpeqi cmpnei cmpgei cmpgeui cmpgti cmpgtui cmplei cmpleui cmplti cmpltui	These instructions are immediate versions of the comparison operations. They compare the value of a register and a 16-bit immediate value. Signed operations sign-extend the immediate value to 32-bits. Unsigned operations fill the upper bits with zero.

Shift and Rotate Instructions

The following instructions provide shift and rotate operations. The number of bits to rotate or shift can be specified in a register or an immediate value.

Table 3-46: Shift and Rotate Instructions

Instruction	Description
rol ror roli	The rol and roli instructions provide left bit-rotation. roli uses an immediate value to specify the number of bits to rotate. The ror instructions provides right bit-rotation. There is no immediate version of ror, because roli can be used to implement the equivalent operation.
sll slli sra srl srai srli	These shift instructions implement the << and >> operators of the C programming language. The sll, slli, srl, srli instructions provide left and right logical bit-shifting operations, inserting zeros. The sra and srai instructions provide arithmetic right bit-shifting, duplicating the sign bit in the most significant bit. slli, srli and srai use an immediate value to specify the number of bits to shift.

Program Control Instructions

The Nios II architecture supports the unconditional jump, branch, and call instructions. These instructions do not have delay slots.

Table 3-47: Unconditional Jump and Call Instructions

Instruction	Description
call	This instruction calls a subroutine using an immediate value as the subroutine's absolute address, and stores the return address in register ra.
callr	This instruction calls a subroutine at the absolute address contained in a register, and stores the return address in register ra. This instruction serves the roll of dereferencing a C function pointer.
ret	The ret instruction is used to return from subroutines called by call or callr. ret loads and executes the instruction specified by the address in register ra.

Instruction	Description
jmp	The `jmp` instruction jumps to an absolute address contained in a register. `jmp` is used to implement switch statements of the C programming language.
jmpi	The `jmpi` instruction jumps to an absolute address using an immediate value to determine the absolute address.
br	This instruction branches relative to the current instruction. A signed immediate value gives the offset of the next instruction to execute.

The conditional branch instructions compare register values directly, and branch if the expression is true. The conditional branches support the following equality and relational comparisons of the C programming language:

- == and !=
- < and <= (signed and unsigned)
- > and >= (signed and unsigned)

The conditional branch instructions do not have delay slots.

Table 3-48: Conditional Branch Instructions

Instruction	Description
bge bgeu bgt bgtu ble bleu blt bltu beq bne	These instructions provide relative branches that compare two register values and branch if the expression is true. Refer to the "Comparison Instructions" section of this chapter for a description of the relational operations implemented.

Related Information

Other Control Instructions

Table 3-49: Other Control Instructions

Instruction	Description
trap eret	The `trap` and `eret` instructions generate and return from exceptions. These instructions are similar to the `call/ret` pair, but are used for exceptions. `trap` saves the `status` register in the `estatus` register, saves the return address in the `ea` register, and then transfers execution to the general exception handler. `eret` returns from exception processing by restoring `status` from `estatus`, and executing the instruction specified by the address in `ea`.

Instruction	Description
break bret	The break and bret instructions generate and return from breaks. break and bret are used exclusively by software debugging tools. Programmers never use these instructions in application code.
rdctl wrctl	These instructions read and write control registers, such as the status register. The value is read from or stored to a general-purpose register.
flushd flushda flushi initd initda initi	These instructions are used to manage the data and instruction cache memories.
flushp	This instruction flushes all prefetched instructions from the pipeline. This is necessary before jumping to recently-modified instruction memory.
sync	This instruction ensures that all previously-issued operations have completed before allowing execution of subsequent load and store operations.
rdprs wrprs	These instructions read and write a general-purpose registers between the current register set and another register set. wrprs can set r0 to 0 in a shadow register set. System software must use wrprs to initialize r0 to 0 in each shadow register set before using that register set.

Custom Instructions

The custom instruction provides low-level access to custom instruction logic. The inclusion of custom instructions is specified with the Nios II Processor parameter editor in Qsys, and the function implemented by custom instruction logic is design dependent.

For more information, refer to the "Custom Instructions" section of the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*

For continued more information refer to the *Nios II Custom Instruction User Guide.*

Machine-generated C functions and assembly language macros provide access to custom instructions, and hide implementation details from the user. Therefore, most software developers never use the custom assembly language instruction directly.

Related Information

- **Nios II Custom Instruction User Guide**
- **Processor Architecture** on page 2-1

No-Operation Instruction

The Nios II assembler provides a no-operation instruction, nop.

Potential Unimplemented Instructions

Some Nios II processor cores do not support all instructions in hardware. In this case, the processor generates an exception after issuing an unimplemented instruction. Only the following instructions can generate an unimplemented instruction exception:

- `mul`
- `muli`
- `mulxss`
- `mulxsu`
- `mulxuu`
- `div`
- `divu`
- `initda`

All other instructions are guaranteed not to generate an unimplemented instruction exception.

An exception routine must exercise caution if it uses these instructions, because they could generate another exception before the previous exception is properly handled.

Refer to the "Unimplemented Instruction" section of this chapter for more information regarding unimplemented instruction processing.

This chapter describes the Nios II Gen2 Processor parameter editor in Qsys. The Nios II Processor parameter editor allows you to specify the processor features for a particular Nios II hardware system. This chapter covers the features of the Nios II processor that you can configure with the Nios II Processor parameter editor; it is not a user guide for creating complete Nios II processor systems.

To get started designing custom Nios II systems, refer to the Nios II Hardware Development Tutorial.

Development kits for Altera devices, available on the All Development Kits page of the Altera website, also provide ready-made hardware design examples that demonstrate different configurations of the Nios II processor.

Nios II Hardware Development Tutorial

Main Nios II Gen2 Tab

The main purpose of the **Main** tab is to select the processor core. The core you select on this tab affects other options available on this and other tabs.

ISO
9001:2008
Registered

ALTERA
now part of Intel

Figure 4-1: Nios II Gen2 Qsys Main Tab
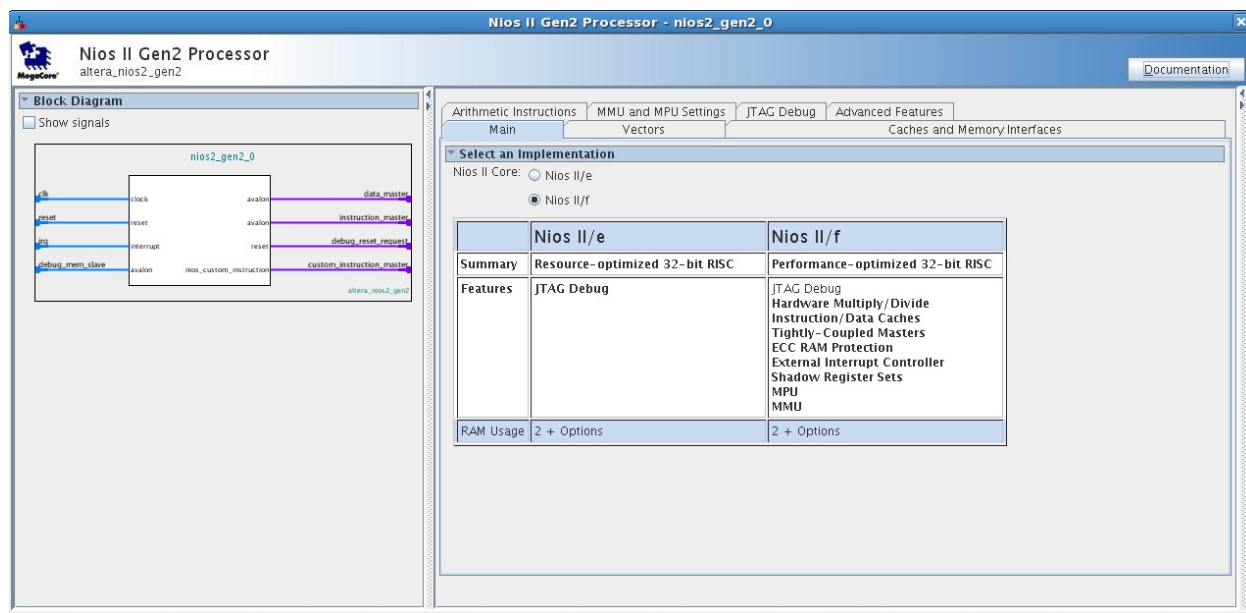

Altera offers the following Nios II cores:

- **Nios II/f**—The Nios II/f **fast** core is designed for fast performance. As a result, this core presents the most configuration options allowing you to fine tune the processor for performance.
- **Nios II/e**—The Nios II/e **economy** core is designed to achieve the smallest possible core size. As a result, this core has a limited feature set, and many settings are not available when the Nios II/e core is selected.

The **Main** tab displays a selector guide table that lists the basic properties of each core.

For implementation information about each core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Nios II Core Implementation Details on page 5-1

Vectors Tab

Figure 4-2: Nios II Gen2 Qsys Vector Tab

Reset Vector

Parameters in this section select the memory module where the reset code (boot loader) resides, and the location of the reset vector (reset address). The reset vector cannot be configured until your system memory components are in place.

The **Reset vector memory** list, which includes all memory modules mastered by the Nios II processor, selects the reset vector memory module. In a typical system, select a nonvolatile memory module for the reset code.

Reset vector offset specifies the location of the reset vector relative to the memory module's base address. Qsys calculates the physical address of the reset vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, **Reset vector** displays the read-only, calculated address. The address is always a physical address, even when an MMU is present.

Note: Qsys provides an **Absolute** option, which allows you to specify an absolute address in **Reset vector offset**. Use an absolute address when the memory storing the reset handler is located outside of the processor system and subsystems of the processor system.

For information about reset exceptions, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Exception Vector

Parameters in this section select the memory module where the general exception vector (exception address) resides, and the location of the general exception vector. The general exception vector cannot be configured until your system memory components are in place.

The **Exception vector memory** list, which includes all memory modules mastered by the Nios II processor, selects the exception vector memory module. In a typical system, select a low-latency memory module for the exception code.

Exception vector offset specifies the location of the exception vector relative to the memory module's base address. Qsys calculates the physical address of the exception vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, **Exception vector** displays the read-only, calculated address.. The address is always a physical address, even when an MMU is present.

Note: Qsys provides an **Absolute** option, which allows you to specify an absolute address in **Exception vector offset**. Use an absolute address when the memory storing the exception handler is located outside of the processor system and subsystems of the processor system.

For information about exceptions, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Fast TLB Miss Exception Vector

The fast TLB miss exception vector is a special exception vector used exclusively by the MMU to handle TLB miss exceptions. Parameters in this section select the memory module where the fast TLB miss exception vector (exception address) resides, and the location of the fast TLB miss exception vector. The fast TLB miss exception vector cannot be configured until your system memory components are in place.

The Fast TLB Miss Exception vector memory list, which includes all memory modules mastered by the Nios II processor, selects the exception vector memory module. In a typical system, select a low-latency memory module for the exception code.

Note: Qsys provides an Absolute option, which allows you to specify an absolute address in Fast TLB Miss Exception vector offset. Use an absolute address when the memory storing the exception handler is located outside of the processor system and subsystems of the processor system.

Fast TLB Miss Exception vector offset specifies the location of the exception vector relative to the memory module's base address. Qsys calculates the physical address of the exception vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, Fast TLB Miss Exception vector displays the readonly, calculated address. The address is always a physical address, even when an MMU is present.

Note: The Nios II MMU is optional and mutually exclusive from the Nios II MPU. Nios II systems can include either an MMU or MPU, but cannot include both an MMU and MPU in the same design.

For information about the Nios II MMU, refer to the *Programming Model* chapter of the Nios II Processor Reference Handbook.

To function correctly with the MMU, the base physical address of all exception vectors (reset, general exception, break, and fast TLB miss) must point to low physical memory so that hardware can correctly

map their virtual addresses into the kernel partition. This restriction is enforced by the Nios II Processor parameter editor.

Related Information
Programming Model on page 3-1

Caches and Memory Interfaces Tab

The **Caches and Memory Interfaces** tab allows you to configure the cache and tightly-coupled memory usage for the instruction and data master ports.

Figure 4-3: Nios II Gen2 Qsys Caches and Memory Interfaces Tab

Instruction Cache

The Instruction cache parameters provide the following options for the Nios II/f core:

- **Size**—Specifies the size of the instruction cache. Valid sizes are from 512 bytes to 64 KBytes, or None.

  Choosing None disables the instruction cache. The Avalon-MM instruction master port from the Nios II processor will still available. In this case, you must include a tightly-coupled instruction memory.
- **Add burstcount signal to instruction_master** —The Nios II processor can fill its instruction cache lines using burst transfers. Usually you enable bursts on the processor's instruction master when instructions are stored in DRAM, and disable bursts when instructions are stored in SRAM.

  Bursting to DRAM typically improves memory bandwidth, but might consume additional FPGA resources. Be aware that when bursts are enabled, accesses to slaves might go through additional hardware (called burst adapters) which might decrease your f_{MAX}.

  When the Nios II processor transfers execution to the first word of a cache line, the processor fills the line by executing a sequence of word transfers that have ascending addresses, such as 0, 4, 8, 12, 16, 20, 24, 28.

  However, when the Nios II processor transfers execution to an instruction that is not the first word of a cache line, the processor fetches the required (or "critical") instruction first, and then fills the rest of the cache line. The addresses of a burst increase until the last word of the cache line is filled, and then continue with the first word of the cache line. For example, with a 32-byte cache line, transferring control to address 8 results in a burst with the following address sequence: 8, 12, 16, 20, 24, 28, 0, 4.

Flash Accelerator

The Flash accelerator is a small fully-associative cache for real-time applications. Use the Flash accelerator when executing directly from on-chip memories such as flash.

You can choose either 64-bits or 128-bits for your line size option. After choosing a line size you are able to choose either 2 or 4 cache lines for your system. After instantiating the Flash Accelerator the `flash_instruction_master` signal becomes available.

Note: It is recommended to use the Flash Accelerator with MAX 10 on-chip flash.

Data Cache

The **Data Cache** parameters provide the following options for the Nios II/f core:

- **Size**—Specifies the size of the data cache. Valid sizes are from 512 bytes to 64 KBytes, or None. Depending on the value specified for Data cache, the following options are available:
- **Victim buffer implementation**—Specifies whether to use RAM or registers. The data cache victim buffer temporarily holds a dirty cache line while the data is written back to external memory.
- **Add burstcount signal to data_master**—The Nios II processor can fill its data cache lines using burst transfers. Usually you enable bursts on the processor's data bus when processor data is stored in DRAM, and disable bursts when processor data is stored in SRAM.

  Bursting to DRAM typically improves memory bandwidth but might consume additional FPGA resources. Be aware that when bursts are enabled, accesses to slaves might go through additional hardware (called burst adapters) which might decrease your fMAX.

  The burst length is always 8 for a 32-byte line size. Data cache bursts are always aligned on the cache line boundary. For example, with a 32-byte Nios II data cache line, a cache miss to the address 8 results in a burst with the following address sequence: 0, 4, 8, 12, 16, 20, 24 and 28.
- **Use most-significant address bit in processor to bypass data cache**—This option is enabled by default, the data master interfaces only support up to 31-bit byte address. Disable this option to support full 32-bit byte address

Although the Nios II processor can operate entirely out of tightly-coupled memory without the need for Avalon-MM instruction or data masters, software debug is not possible when either the Avalon-MM instruction or data master is omitted.

Note: By default this feature is turned on for backwards compatibility with the Nios II Classic core.

Tightly-coupled Memories

Number of tightly coupled instruction master port(s) (**Include tightly coupled instruction master port(s)**)—Specifies one to four tightly-coupled instruction master ports for the Nios II Gen2 processor. In Qsys, select the number from the **Number of tightly coupled instruction master port(s)** list. Tightly coupled memory ports appear on the connection panel of the Nios II Gen2 processor on the Qsys System Contents tab. You must connect each port to exactly one memory component in the system.

Peripheral Region

The Peripheral Region section in the Caches and Memory Interfaces tab has a maximum size of 2 Gbytes. You can set the base address once the size has been selected. All addresses in the peripheral region produce uncacheable data accesses.

Arithmetic Instructions Tab

Nios II/f cores offer hardware multiply and divide options. You can choose the best option to balance embedded multiplier usage, logic element (LE) usage, and performance.

Figure 4-4: Nios II Gen2 Qsys Arithmetic Instructions Tab

Arithmetic Instructions

- **Multiply/Shift/Rotate Hardware:**—You have the option of either choosing auto or manually selected hardware. It is recommended to choose auto, which selects the hardware according to the device family in your current Qsys project.
- **Divide Hardware:**—Qsys allows you to choose SRT Radix-2 as your divide hardware option if selected.

Table 4-1: Divide Hardware: SRT Radix-2

Hardware	Performance	Resources	Instructions
32-bit divide	35 cycles	Logic elements	All Divide

Arithmetic Implementation

This section is only available if you choose to manually select your multiply/shift/rotate hardware.

- **32-bit multiply instruction implementation**—You have three options for the 32-bit multiply instruction. Choosing the 1 32-bit multiplier option allocates all resources to the 32-bit multiplier making it the resource for the 64-bit multiply instruction and shift/rotate instruction.

Table 4-2: 32-bit multiply instruction implementation options

Performance	Resources	Instruction
11 cycles	Logic elements	All 32-bit Multiply
1 cycle	3 16-bit multipliers	All 32-bit Multiply
1 cycle	1 32-bit multipliers	All 32-bit Multiply

- **64-bit multiply instruction implementation**— This option can only be used if the 32-bit multiply instruction selection is set to the 3 16-bit multipliers option. The Nios II only supports up to a 32 x 32 bit multiplication. The 64-bit option is achieved by using the 32-bit multiplier along with the multiply extended instructions (`mulxss`, `mulxsu`, `mulxuu`), which can be found in the *Instruction Set Reference* chapter of this manual.

Table 4-3: 64-bit multiply instruction implementation options

Performance	Resources	Instruction
2 cycles	1 16-bit multiplier	All 64-bit Multiply

- **Shift/rotate instruction implementation**—Qsys gives you the option of either choosing non-pipelined or pipelined.

Table 4-4: Shift/rotate instruction implementation options

Performance	Resources	Instructions
2 - 11 cycles	Logic elements (non-pipelined)	All Shift/Rotate
1 cycle	Logic elements (pipelined)	All Shift/Rotate

Note: Highly recommend to chose auto selection. Qsys will make the selections according to the device family previously selected.

MMU and MPU Settings Tab

The **MMU and MPU Settings** tab presents settings for configuring the MMU and MPU on the Nios II Gen2 processor. You can select the features appropriate for your target application.

Figure 4-5: Nios II Gen2 Qsys MMU and MPU Settings Tab

Note: This tab is only avaliable for the Nios II/f core.

MMU

When **Include MMU** on the **MMU and MPU Settings** tab is on, the MMU settings on the **MMU and MPU Settings** tab provide the following options for the MMU in the Nios II/f core. Typically, you should not need to change any of these settings from their default values.

- **Process ID (PID) bits**—Specifies the number of bits to use to represent the process identifier.
- **Optimize number of TLB entries based on device family**—When on, specifies the optimal number of TLB entries to allocate based on the device family of the target hardware and disables **TLB entries**.
- **TLB entries**—Specifies the number of entries in the translation lookaside buffer (TLB).
- **TLB Set-Associativity**—Specifies the number of set-associativity ways in the TLB.
- **Micro DTLB entries**—Specifies the number of entries in the micro data TLB.
- **Micro ITLB entries**—Specifies the number of entries in the micro instruction TLB.

For information about the MMU, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

For specifics on the Nios II/f core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Related Information

- **Programming Model** on page 3-1

- **Nios II Core Implementation Details** on page 5-1

MPU

When **Include MPU** on the **MMU and MPU Settings** tab is on, the MPU settings on the **MMU and MPU Settings** tab provide the following options for the MPU in the Nios II/f core.

- **Use Limit for region range**—Controls whether the amount of memory in the region is defined by size or by upper address limit. When on, the amount of memory is based on the given upper address limit. When off, the amount of memory is based on the given size.
- **Number of data regions**—Specifies the number of data regions to allocate. Allowed values range from 2 to 32.
- **Minimum data region size**—Specifies the minimum data region size. Allowed values range from 256 bytes to 1 MB and must be a power of two.
- **Number of instruction regions**—Specifies the number of instruction regions to allocate. Allowed values range from 2 to 32.
- **Minimum instruction region size**—Specifies the minimum instruction region size. Allowed values range from 256 bytes to 1 MB and must be a power of two.

Note: The maximum region size is the size of the Nios II instruction and data addresses automatically determined when the Nios II system is generated in Qsys. Maximum region size is based on the address range of slaves connected to the Nios II instruction and data masters.

For information about the MPU, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

For specifics on the Nios II/f core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

JTAG Debug Tab

The **JTAG Debug** tab presents settings for configuring the JTAG debug module on the Nios II Gen2 processor. You can select the debug features appropriate for your target application.

Figure 4-6: Nios II Gen2 Qsys JTAB Debug Tab

Soft processor cores such as the Nios II Gen2 processor offer unique debug capabilities beyond the features of traditional fixed processors. The soft nature of the Nios II processor allows you to debug a system in development using a full-featured debug core, and later remove the debug features to conserve logic resources. For the release version of a product, you might choose to reduce the JTAG debug module functionality, or remove it altogether.

Table 4-5: Debug Configuration Features

Feature	Description
JTAG Target Connection	Connects to the processor through the standard JTAG pins on the Altera FPGA. This connection provides the basic capabilities to start and stop the processor, and examine/edit registers and memory.
Download Software	Downloads executable code to the processor's memory via the JTAG connection.
Software Breakpoints	Sets a breakpoint on instructions residing in RAM.
Hardware Breakpoints	Sets a breakpoint on instructions residing in nonvolatile memory, such as flash memory.

Feature	Description
Data Triggers	Triggers based on address value, data value, or read or write cycle. You can use a trigger to halt the processor on specific events or conditions, or to activate other events, such as starting execution trace, or sending a trigger signal to an external logic analyzer. Two data triggers can be combined to form a trigger that activates on a range of data or addresses.
Instruction Trace	Captures the sequence of instructions executing on the processor in real time.
Data Trace	Captures the addresses and data associated with read and write operations executed by the processor in real time.
On-Chip Trace	Stores trace data in on-chip memory.
Off-Chip Trace	Stores trace data in an external debug probe. Off-chip trace instantiates a PLL inside the Nios II core. Off-chip trace requires a debug probe from Imagination Technologies or Lauterbach GmbH.

The **Include debugreq and debugack signals** debug signals setting provides the following functionality. When on, the Nios II processor includes debug request and acknowledge signals. These signals let another device temporarily suspend the Nios II processor for debug purposes. The signals are exported to the top level of your Qsys system.

For more information about the debug signals, refer to the Processor Architecture chapter of the Nios II Processor Reference Handbook.

You can set the onchip trace buffer size to sizes from 128 to 64K trace frames, using OCI Onchip Trace. Larger buffer sizes consume more on-chip M4K RAM blocks. Every M4K RAM block can store up to 128 trace frames.

Advanced Features Tab

Figure 4-7: Nios II Gen2 Qsys Advanced Features Tab

ECC

ECC is only available for the Nios II/f core and provides ECC support for Nios II internal RAM blocks, such as instruction cache, MMU TLB, and register file. The SECDED ECC algorithm is based on Hamming codes, which detect 1 or 2 bit errors and corrects 1 bit errors. If the Nios II processor does not attempt to correct any errors and only detects them, the ECC algorithm can detect 3 bit errors.

Refer to "ECC" section in the Nios II Core Implementation Details chapter for more information about ECC support in the Nios II/f core.

Related Information
ECC on page 5-14

Interrupt Controller Interfaces

The Interrupt controller setting determines which of the following configurations is implemented:

- Internal interrupt controller
- External interrupt controller (EIC) interface

The EIC interface is available only on the Nios II/f core.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the latest Nios II Embedded Design Suite (EDS) version. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

For details about the EIC interface, refer to "Exception Processing" in the Programming Model chapter of the Nios II Processor Reference Handbook.

Related Information

Exception Processing on page 3-38

Shadow Register Sets

The Number of shadow register sets setting determines whether the Nios II core implements shadow register sets. The Nios II core can be configured with up to 63 shadow register sets.

Shadow register sets are available only on the Nios II/f core.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or higher.

For details about shadow register sets, refer to "Registers" in the Programming Model chapter of the Nios II Processor Reference Handbook.

Related Information

Registers on page 3-9

Reset Signals

The Include **cpu_resetrequest** and **cpu_resettaken** signals reset signals setting provides the following functionality. When on, the Nios II processor includes processor-only reset request signals. These signals let another device individually reset the Nios II processor without resetting the entire system. The signals are exported to the top level of your system.

Note: You must manually connect these signals to logic external to your Qsys system.

For more information on the reset signals, refer to the Processor Architecture chapter of the Nios II Processor Reference Handbook.

Related Information

Processor Architecture on page 2-1

CPU ID Control Register Value

In Qsys, the automatically-assigned CPUID control register value is always 0x00000000, so Altera recommends always assigning the value manually.

To assign the value yourself, turn on Assign cpuid control register value manually and type a 32-bit value (in hexadecimal or decimal format) in the cpuid control register value box.

Generate Trace File

Through this selection, Qsys creates a trace file called `"system_name"_"cpu_name".tr`. Use the `nios2-trace` command to display it.

Exception Checking

The Exception Checking settings provide the following options:

Misaligned memory access—Misaligned memory access detection is only available for the Nios II/f core. When Misaligned memory access is on, the processor checks for misaligned memory accesses.

Note: When your system contains an MMU or MPU, the processor automatically generates misaligned memory access exceptions. Therefore, the **Misaligned memory access** check box is always disabled when **Include MMU** or **Include MPU** on the **Core Nios II** tab are on.

There are two misaligned memory address exceptions:

- Misaligned data address—Data addresses of load and store instructions are checked for misalignment. A data address is considered misaligned if the byte address is not a multiple of the data width of the load or store instruction (4 bytes for word, 2 bytes for half-word). Byte load and store instructions are always aligned so never generate a misaligned data address exception.
- Misaligned destination address—Destination instruction addresses of `br`, `callr`, `jmp`, `ret`, `eret`, and `bret` instructions are checked for misalignment. A destination instruction address is considered misaligned if the target byte address of the instruction is not a multiple of four.

Your exception handler can use this code to quickly determine the proper action to take, rather than have to determine the cause of an exception through instruction decoding. Additionally, some exceptions also store the instruction or data address associated with the exception in the `badaddr` register.

For further descriptions of exceptions, exception handling, and control registers, refer to the Programming Model chapter of the Nios II Processor Reference Handbook.

Programming Model on page 3-1

Branch Prediction

This section in the tab allows you to choose either dynamic or static for your branch prediction type. As for the number of entries (2-bits wide) you can choose to have 256, 4096, or up to 8192 entries.

RAM Memory Protection

Through the RAM Memory Protection section you can include the `reset_req` signal for OCI RAM and Multi-Cycle Custom Instructions.

The Quartus Prime IP File

The Quartus® Prime IP file (`.qip`) is a file generated by the MegaWizard™ Plug-In Manager, that contains information about a generated IP core. You are prompted to add this `.qip` file to the current project at the time of Quartus Prime file generation. In most cases, the `.qip` file contains all of the necessary assignments and information required to process the core or system in the Quartus Prime compiler. Generally, a single `.qip` file is generated for each MegaCore function and for each Qsys system. However, some complex components generate a separate `.qip` file, so the system `.qip` file references the component `.qip` file.

---

[41] Multiply and shift performance depends on the hardware multiply option you use. If no hardware multiply option is used, multiply operations are emulated in software, and shift operations require one cycle per bit. For details, refer to the arithmetic logic unit description for each core.

Device Family	Support
Stratix IV E	Final
Stratix IV GT	Final
Stratix IV GX	Final
Stratix V	Final

Preliminary support—The core is verified with preliminary timing models for this device family. The core meets all functional requirements, but might still be undergoing timing analysis for the device family. It can be used in production designs with caution.

Final support—The core is verified with final timing models for this device family. The core meets all functional and timing requirements for the device family and can be used in production designs.

Nios II/f Core

The Nios II/f fast core is designed for high execution performance. Performance is gained at the expense of core size. Altera designed the Nios II/f core with the following design goals in mind:

- Maximize the instructions-per-cycle execution efficiency
- Optimize interrupt latency
- Maximize f_{MAX} performance of the processor core

The resulting core is optimal for performance-critical applications, as well as for applications with large amounts of code and/or data, such as systems running a full-featured operating system.

Overview

The Nios II/f core:

- Has separate optional instruction and data caches
- Provides optional MMU to support operating systems that require an MMU
- Provides optional MPU to support operating systems and runtime environments that desire memory protection but do not need virtual memory management
- Can access up to 4 GB of external address space when bit31 is not enabled
- Supports optional external interrupt controller (EIC) interface to provide customizable interrupt prioritization
- Supports optional shadow register sets to improve interrupt latency
- Supports optional tightly-coupled memory for instructions and data
- Employs a 6-stage pipeline to achieve maximum DMIPS/MHz
- Performs dynamic or static branch prediction
- Provides optional hardware multiply, divide, and shift options to improve arithmetic performance
- Supports the addition of custom instructions
- Optional ECC support for internal RAM blocks (data cache, data cache victim buffer RAM, instruction and data tightly-coupled memories, instruction cache, MMU TLB, and register file)
- Supports the JTAG debug module
- Supports optional JTAG debug module enhancements, including hardware breakpoints and real-time trace

The following sections discuss the noteworthy details of the Nios II/f core implementation. This document does not discuss low-level design issues or implementation details that do not affect Nios II hardware or software designers.

Arithmetic Logic Unit

The Nios II/f core provides several arithmetic logic unit (ALU) options to improve the performance of multiply, divide, and shift operations.

Multiply and Divide Performance

The Nios II/f core provides the following hardware multiplier options:

- DSP Block—Includes DSP block multipliers available on the target device. This option is available only on Altera FPGAs that have a hardware multiplier that supports 32-bit multiplication.
- Embedded Multipliers—Includes dedicated embedded multipliers available on the target device. This option is available only on Altera FPGAs that have embedded multipliers.
- Logic Elements—Includes hardware multipliers built from logic element (LE) resources.
- None—Does not include multiply hardware. In this case, multiply operations are emulated in software.

The Nios II/f core also provides a hardware divide option that includes LE-based divide circuitry in the ALU.

Including an ALU option improves the performance of one or more arithmetic instructions.

Note: The performance of the embedded multipliers differ, depending on the target FPGA family.

Table 5-3: Hardware Multiply and Divide Details for the Nios II/f Core

ALU Option	Hardware Details	Cycles per Instruction	Result Latency Cycles	Supported Instructions
No hardware multiply or divide	Multiply and divide instructions generate an exception	–	–	None
Logic elements	ALU includes 32 x 4-bit multiplier	11	+2	`mul, muli`
32-bit multiplier	ALU includes 32 x 32-bit multiplier	1	+2	`mul, muli, mulxss, mulxsu, mulxuu`
16-bit multiplier	ALU includes 3 16 x 16-bit multiplier	1	+2	`mul, muli`
16-bit multiplier	ALU includes 4 16 x 16-bit multiplier	2	+2	`mul, muli, mulxss, mulxsu, mulxuu`
Hardware divide	ALU includes SRT Radix-2 divide circuit	35	+2	`div, divu`

The cycles per instruction value determines the maximum rate at which the ALU can dispatch instructions and produce each result. The latency value determines when the result becomes available. If there is no data dependency between the results and operands for back-to-back instructions, then the latency does not affect throughput. However, if an instruction depends on the result of an earlier instruction, then the processor stalls through any result latency cycles until the result is ready.

In the following code example, a multiply operation (with 1 instruction cycle and 2 result latency cycles) is followed immediately by an add operation that uses the result of the multiply. On the Nios II/f core, the `addi` instruction, like most ALU instructions, executes in a single cycle. However, in this code example, execution of the `addi` instruction is delayed by two additional cycles until the multiply operation completes.

```
mul  r1, r2, r3        ; r1 = r2 * r3
addi r1, r1, 100       ; r1 = r1 + 100 (Depends on result of mul)
```

In contrast, the following code does not stall the processor.

```
mul  r1, r2, r3        ; r1 = r2 * r3
or   r5, r5, r6        ; No dependency on previous results
or   r7, r7, r8        ; No dependency on previous results
addi r1, r1, 100       ; r1 = r1 + 100 (Depends on result of mul)
```

Shift and Rotate Performance

The performance of shift operations depends on the hardware multiply option. When a hardware multiplier is present, the ALU achieves shift and rotate operations in three or four clock cycles. Otherwise, the ALU includes dedicated shift circuitry that achieves one-bit-per-cycle shift and rotate performance.

Related Information

Instruction Performance on page 5-12

Memory Access

The Nios II/f core provides optional instruction and data caches. The cache size for each is user-definable, between 512 bytes and 64 KB.

The memory address width in the Nios II/f core depends on whether the optional MMU is present. Without an MMU, the Nios II/f core supports the bit-31 cache bypass method for accessing I/O on the data master port. Therefore addresses are 31 bits wide, reserving bit 31 for the cache bypass function. With an MMU, cache bypass is a function of the memory partition and the contents of the translation lookaside buffer (TLB). Therefore bit-31 cache bypass is disabled, and 32 address bits are available to address memory.

Instruction and Data Master Ports

The instruction master port is a pipelined Avalon Memory-Mapped (Avalon-MM) master port. The core also includes a data cache with a fixed 32-byte line size, making he data master port a pipelined Avalon-MM master port.

The instruction and data master ports on the Nios II/f core are optional. A master port can be excluded, as long as the core includes at least one tightly-coupled memory to take the place of the missing master port.

Note: Although the Nios II processor can operate entirely out of tightly-coupled memory without the need for Avalon-MM instruction or data masters, software debug is not possible when either the Avalon-MM instruction or data master is omitted.

Support for pipelined Avalon-MM transfers minimizes the impact of synchronous memory with pipeline latency. The pipelined instruction and data master ports can issue successive read requests before prior requests complete.

Instruction and Data Caches

This section first describes the similar characteristics of the instruction and data cache memories, and then describes the differences.

Both the instruction and data cache addresses are divided into fields based on whether or not an MMU is present in your system.

Table 5-4: Cache Byte Address Fields

Bit Fields

											offset				

Instruction Cache

The instruction cache memory has the following characteristics:

- Direct-mapped cache implementation.
- 32 bytes (8 words) per cache line.
- The instruction master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Critical word first.
- Virtually-indexed, physically-tagged, when MMU present.

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The offset field is always five bits (i.e., a 32-byte line). The maximum instruction byte address size is 31 bits in systems without an MMU present. In

systems with an MMU, the maximum instruction byte address size is 32 bits and the tag field always includes all the bits of the physical frame number (PFN).

The instruction cache is optional. However, excluding instruction cache from the Nios II/f core requires that the core include at least one tightly-coupled instruction memory.

Data Cache

- Direct-mapped cache implementation
- Line size of 32-bytes
- The data master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Write-back
- Write-allocate (i.e., on a store instruction, a cache miss allocates the line for that address)
- Virtually-indexed, physically-tagged, when MMU present

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The size of the offset field depends on the line size. Line sizes of 32 bytes have offset widths of 5-bits. The maximum data byte address size is 31 bits in systems without an MMU present. In systems with an MMU, the maximum data byte address size is 32 bits and the tag field always includes all the bits of the PFN.

The data cache is optional. If the data cache is excluded from the core, the data master port can also be excluded.

The Nios II instruction set provides several different instructions to clear the data cache. There are two important questions to answer when determining the instruction to use. Do you need to consider the tag field when looking for a cache match? Do you need to write dirty cache lines back to memory before clearing? Below the table lists the most appropriate instruction to use for each case.

Table 5-7: Data Cache Clearing Instructions

Instruction	Ignore Tag Field	Consider Tag Field
Write Dirty Lines	`flushd`	`flushda`
Do Not Write Dirty Lines	`initd`	`initda`

For more information regarding the Nios II instruction set, refer to the *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook*.

The Nios II/f core implements all the data cache bypass methods.

For information regarding the data cache bypass methods, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*

Mixing cached and uncached accesses to the same cache line can result in invalid data reads. For example, the following sequence of events causes cache incoherency.

1. The Nios II core writes data to cache, creating a dirty data cache line.
2. The Nios II core reads data from the same address, but bypasses the cache.

Note: Avoid mixing cached and uncached accesses to the same cache line, regardless whether you are reading from or writing to the cache line. If it is necessary to mix cached and uncached data accesses, flush the corresponding line of the data cache after completing the cached accesses and before performing the uncached accesses.

Related Information

- **Instruction Set Reference** on page 8-1
- **Processor Architecture** on page 2-1

Bursting

When the data cache is enabled, you can enable bursting on the data master port. Consult the documentation for memory devices connected to the data master port to determine whether bursting can improve performance.

Tightly-Coupled Memory

The Nios II/f core provides optional tightly-coupled memory interfaces for both instructions and data. A Nios II/f core can use up to four each of instruction and data tightly-coupled memories. When a tightly-coupled memory interface is enabled, the Nios II core includes an additional memory interface master port. Each tightly-coupled memory interface must connect directly to exactly one memory slave port.

When tightly-coupled memory is present, the Nios II core decodes addresses internally to determine if requested instructions or data reside in tightly-coupled memory. If the address resides in tightly-coupled memory, the Nios II core fetches the instruction or data through the tightly-coupled memory interface. Software accesses tightly-coupled memory with the usual load and store instructions, such as `ldw` or `ldwio`.

Accessing tightly-coupled memory bypasses cache memory. The processor core functions as if cache were not present for the address span of the tightly-coupled memory. Instructions for managing cache, such as `initd` and `flushd`, do not affect the tightly-coupled memory, even if the instruction specifies an address in tightly-coupled memory.

When the MMU is present, tightly-coupled memories are always mapped into the kernel partition and can only be accessed in supervisor mode.

Memory Management Unit

The Nios II/f core provides options to improve the performance of the Nios II MMU.

For information about the MMU architecture, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Micro Translation Lookaside Buffers

The translation lookaside buffer (TLB) consists of one main TLB stored in on-chip RAM and two separate micro TLBs (μTLB) for instructions μITLB) and data (μDTLB) stored in LE-based registers.

The TLBs have a configurable number of entries and are fully associative. The default configuration has 6 μDTLB entries and 4 μITLB entries. The hardware chooses the least-recently used μTLB entry when loading a new entry.

The μTLBs are not visible to software. They act as an inclusive cache of the main TLB. The processor firsts look for a hit in the μTLB. If it misses, it then looks for a hit in the main TLB. If the main TLB misses, the processor takes an exception. If the main TLB hits, the TLB entry is copied into the μTLB for future accesses.

The hardware automatically flushes the µTLB on each TLB write operation and on a `wrctl` to the `tlbmisc` register in case the process identifier (PID) has changed.

Memory Protection Unit

The Nios II/f core provides options to improve the performance of the Nios II MPU.

For information about the MPU architecture, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information
Programming Model on page 3-1

Execution Pipeline

This section provides an overview of the pipeline behavior for the benefit of performance-critical applications. Designers can use this information to minimize unnecessary processor stalling. Most application programmers never need to analyze the performance of individual instructions.

The Nios II/f core employs a 6-stage pipeline.

Table 5-8: Implementation Pipeline Stages for Nios II/f Core

Stage Letter	Stage Name
F	Fetch
D	Decode
E	Execute
M	Memory
A	Align
W	Writeback

Up to one instruction is dispatched and/or retired per cycle. Instructions are dispatched and retired in order. Dynamic branch prediction is implemented using a 2-bit branch history table. The pipeline stalls for the following conditions:

- Multicycle instructions
- Avalon-MM instruction master port read accesses
- Avalon-MM data master port read/write accesses
- Data dependencies on long latency instructions (e.g., load, multiply, shift).

Pipeline Stalls

The pipeline is set up so that if a stage stalls, no new values enter that stage or any earlier stages. No "catching up" of pipeline stages is allowed, even if a pipeline stage is empty.

Only the A-stage and D-stage are allowed to create stalls.

The A-stage stall occurs if any of the following conditions occurs:

- An A-stage memory instruction is waiting for Avalon-MM data master requests to complete. Typically this happens when a load or store misses in the data cache, or a `flushd` instruction needs to write back a dirty line.
- An A-stage shift/rotate instruction is still performing its operation. This only occurs with the multicycle shift circuitry (i.e., when the hardware multiplier is not available).
- An A-stage divide instruction is still performing its operation. This only occurs when the optional divide circuitry is available.
- An A-stage multicycle custom instruction is asserting its stall signal. This only occurs if the design includes multicycle custom instructions.

The D-stage stall occurs if an instruction is trying to use the result of a late result instruction too early and no M-stage pipeline flush is active. The late result instructions are loads, shifts, rotates, `rdctl`, multiplies (if hardware multiply is supported), divides (if hardware divide is supported), and multicycle custom instructions (if present).

Branch Prediction

The Nios II/f core performs dynamic and static branch predictions to minimize the cycle penalty associated with taken branches.

Instruction Performance

All instructions take one or more cycles to execute. Some instructions have other penalties associated with their execution. Late result instructions have two cycles placed between them and an instruction that uses their result. Instructions that flush the pipeline cause up to three instructions after them to be cancelled. This creates a three-cycle penalty and an execution time of four cycles. Instructions that require Avalon-MM transfers are stalled until any required Avalon-MM transfers (up to one write and one read) are completed.

Table 5-9: Instruction Execution Performance for Nios II/f Core 4byte/line data cache

Instruction	Cycles	Penalties
Normal ALU instructions (e.g., add, cmplt)	1	
Combinatorial custom instructions	1	
Multicycle custom instructions	> 1	Late result
Branch (correctly predicted, taken)	2	
Branch (correctly predicted, not taken)	1	
Branch (mispredicted)	4	Pipeline flush
`trap`, `break`, `eret`, `bret`, `flushp`, `wrctl`, `wrprs`; illegal and unimplemented instructions	4 or 5	Pipeline flush
`call`, `jmpi`, `rdprs`	2	
`jmp`, `ret`, `callr`	3	
`rdctl`	1	Late result
`load` (without Avalon-MM transfer)	1	Late result
`load` (with Avalon-MM transfer)	> 1	Late result

Instruction	Cycles	Penalties
`store` (without Avalon-MM transfer)	1	
`store` (with Avalon-MM transfer)	> 1	
`flushd`, `flushda` (without Avalon-MM transfer)	2	
`flushd`, `flushda` (with Avalon-MM transfer)	> 2	
`initd`, `initda`	2	
`flushi`, `initi`	4	
Multiply		Late result
Divide		Late result
Shift/rotate (with hardware multiply using embedded multipliers)	1	Late result
Shift/rotate (with hardware multiply using LE-based multipliers)	2	Late result
Shift/rotate (without hardware multiply present)	1 to 32	Late result
All other instructions	1	

For Multiply and Divide, the number of cycles depends on the hardware multiply or divide option. Refer to "Arithmetic Logic Unit" and "Instruction and Data Caches" s for details.

In the default Nios II/f configuration, instructions `trap`, `break`, `eret`, `bret`, `flushp`, `wrctl`, `wrprs` require four clock cycles. If any of the following options are present, they require five clock cycles:

- MMU
- MPU
- Division exception
- Misaligned load/store address exception
- EIC port
- Shadow register sets

Related Information

- **Data Cache** on page 5-9
- **Instruction and Data Caches** on page 5-8
- **Arithmetic Logic Unit** on page 5-6

Exception Handling

The Nios II/f core supports the following exception types:

- Hardware interrupts
- Software trap
- Illegal instruction
- Unimplemented instruction
- Supervisor-only instruction (MMU or MPU only)
- Supervisor-only instruction address (MMU or MPU only)
- Supervisor-only data address (MMU or MPU only)
- Misaligned data address
- Misaligned destination address

- Division error
- Error-correcting code (ECC)
- Fast translation lookaside buffer (TLB) miss (MMU only)
- Double TLB miss (MMU only)
- TLB permission violation (MMU only)
- MPU region violation (MPU only)

External Interrupt Controller Interface

The EIC interface enables you to speed up interrupt handling in a complex system by adding a custom interrupt controller.

The EIC interface is an Avalon-ST sink with the following input signals:

- `eic_port_valid`
- `eic_port_data`

Signals are rising-edge triggered, and synchronized with the Nios II clock input.

The EIC interface presents the following signals to the Nios II processor through the `eic_port_data` signal:

- Requested handler address (RHA)—The 32-bit address of the interrupt handler associated with the requested interrupt.
- Requested register set (RRS)—The six-bit number of the register set associated with the requested interrupt.
- Requested interrupt level (RIL)—The six-bit interrupt level. If RIL is 0, no interrupt is requested.
- Requested nonmaskable interrupt (RNMI) flag—A one-bit flag indicating whether the interrupt is to be treated as nonmaskable.

Table 5-10: eic_port_data Signal

Bit Fields															
44	...														
RHA															
...	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RHA		RRS						RNMI	RIL						

Following Avalon-ST protocol requirements, the EIC interface samples `eic_port_data` only when `eic_port_valid` is asserted (high). When `eic_port_valid` is not asserted, the processor latches the previous values of RHA, RRS, RIL and RNMI. To present new values on `eic_port_data`, the EIC must transmit a new packet, asserting `eic_port_valid`. An EIC can transmit a new packet once per clock cycle.

For an example of an EIC implementation, refer to the *Vectored Interrupt Controller* chapter in the Embedded Peripherals IP User Guide.

Related Information
Embedded Peripherals IP User Guide

ECC

The Nios II/f core has the option to add ECC support for the following Nios II internal RAM blocks.

- Instruction cache

  - ECC errors (1, 2, or 3 bits) that occur in the instruction cache are recoverable; the Nios II processor flushes the cache line and reads from external memory instead of correcting the ECC error.
- Register file

  - 1 bit ECC errors are recoverable
  - 2 bit ECC errors are not recoverable and generate ECC exceptions
- MMU TLB

  - 1 bit ECC errors triggered by hardware reads are recoverable
  - 2 bit ECC errors triggered by hardware reads are not recoverable and generate ECC exception.
  - 1 or 2 bit ECC errors triggered by software reads to the TLBMISC register do not trigger an exception, instead, TLBMISC.EE is set to 1. Software must read this field and invalidate/overwrite the TLB entry.
- Data Cache

  - tag RAM—The ECCINJ.DCTAG field is used to inject ECC errors into the tag RAM.
  - data RAM—The ECCINJ.DCDAT field is used to inject ECC errors into the data RAM
- Tightly-Coupled Memories (TCMs)—Nios II includes the ECC encoder/decoder logic for each TCM and the TCM master port data width is increased to allow the Nios II to read and write the ECC parity bits. The TCM must be a RAM and must store the ECC parity bits along with the data bits.

  - Instruction Tightly-Coupled Memories (ITCM)—Nios II supports up to 4 ITCMs
  - Data Tightly-Coupled Memories (DTCM)—Nios II supports up to 4 DTCMs

The ECC interface is an Avalon-ST source with the output signal ecc_event_bus. This interface allows external logic to monitor ECC errors in the Nios II processor.

Table 5-11: ECC Error Signals

Bit	Field	Description	Effect on Software	Available
0	EEH	ECC error exception while in exception handler mode (i.e., STATUS.EH = 1).	Likely fatal	Always
1	RF_RE	Recoverable (1 bit) ECC error in register file RAM	None	Always
2	RF_UE	Unrecoverable (2 bit) ECC error in register file RAM	Likely fatal	Always
3	ICTAG_RE	Recoverable (1, 2, or 3 bit) ECC error in instruction cache tag RAM	None	Instruction cache present
4	ICDAT_RE	Recoverable (1, 2, or 3 bit) ECC error in instruction cache data RAM.	None	Instruction cache present
5	ITCM0_RE	Recoverable (1-bit) ECC error in ITCM0	None	ITCM0 present
6	ITCM0_UE	Unrecoverable (2-bit) ECC error in ITCM0	Possibly fatal	ITCM0 present
7	ITCM1_RE	Recoverable (1-bit) ECC error in ITCM1	None	ITCM1 present

Bit	Field	Description	Effect on Software	Available
8	ITCM1_UE	Unrecoverable (2-bit) ECC error in ITCM1	Likely fatal	ITCM1 present
9	ITCM2_RE	Recoverable (1-bit) ECC error in ITCM2	None	ITCM2 present
10	ITCM2_UE	Unrecoverable (2-bit) ECC error in ITCM2	Likely fatal	ITCM2 present
11	ITCM3_RE	Recoverable (1-bit) ECC error in ITCM3	None	ITCM3 present
12	ITCM3_UE	Unrecoverable (2-bit) ECC error in ITCM3	Likely fatal	ITCM3 present
13	DCTAG_RE	Recoverable (1-bit) ECC error in data cache tag RAM	None	Data cache present
14	DCTAG_UE	Unrecoverable (2-bit) ECC error in data cache tag RAM	Likely fatal	Data cache present
15	DCDAT_RE	Recoverable (1-bit with dirty line, 2-bit or 3-bit with clean line) ECC error in data cache data RAM. Excludes recoverable errors found during writeback of a dirty line.	None	Data cache present
16	DCDAT_UE	Unrecoverable (2-bit with dirty line) ECC error in data cache data RAM. Excludes unrecoverable errors found during writeback of a dirty line.	Likely fatal	Data cache present
17	DCWB_RE	Recoverable (1-bit) ECC error in data cache data RAM or victim line buffer RAM during writeback of a dirty line.	None	Data cache present
18	DCWB_UE	Unrecoverable (2-bit) ECC error in data cache data RAM or victim line buffer RAM during writeback of a dirty line.	Likely fatal	Data cache present
19	TLB_RE	Recoverable (1 bit) ECC error in TLB RAM (hardware read of TLB)	None	MMU present
20	TLB_UE	Unrecoverable (2 bit) ECC error in TLB RAM (hardware read of TLB)	Possibly fatal	MMU present
21	TLB_SW	Software-triggered (1, 2, or 3 bit) ECC error in software read of TLB	Possibly fatal	MMU present
22	DTCM0_RE	Recoverable (1-bit) ECC error in DTCM0	None	DTCM0 present
23	DTCM0_UE	Unrecoverable (2-bit) ECC error in DTCM0	Likely fatal	DTCM0 present
24	DTCM1_RE	Recoverable (1-bit) ECC error in DTCM1	None	DTCM1 present
25	DTCM1_UE	Unrecoverable (2-bit) ECC error in DTCM1	Likely fatal	DTCM1 present
26	DTCM2_RE	Recoverable (1-bit) ECC error in DTCM2	None	DTCM2 present

Bit	Field	Description	Effect on Software	Available
27	DTCM2_UE	Unrecoverable (2-bit) ECC error in DTCM2	Likely fatal	DTCM2 present
28	DTCM3_RE	Recoverable (1-bit) ECC error in DTCM3	None	DTCM3 present
29	DTCM3_UE	Unrecoverable (2-bit) ECC error in DTCM3	Likely fatal	DTCM3 present

JTAG Debug Module

The Nios II/f core supports the JTAG debug module to provide a JTAG interface to software debugging tools. The Nios II/f core supports an optional enhanced interface that allows real-time trace data to be routed out of the processor and stored in an external debug probe.

Note: The Nios II MMU does not support the JTAG debug module trace.

Nios II/e Core

The Nios II/e economy core is designed to achieve the smallest possible core size. Altera designed the Nios II/e core with a singular design goal: reduce resource utilization any way possible, while still maintaining compatibility with the Nios II instruction set architecture. Hardware resources are conserved at the expense of execution performance.

The resulting core is optimal for cost-sensitive applications as well as applications that require simple control logic.

Overview

The Nios II/e core:

- Executes at most one instruction per six clock cycles
- Full 32-bit addressing
- Can access up to 4 GB of external address space
- Supports the addition of custom instructions
- Supports the JTAG debug module
- Does not provide hardware support for potential unimplemented instructions
- Has no instruction cache or data cache
- Does not perform branch prediction

The following sections discuss the noteworthy details of the Nios II/e core implementation. This document does not discuss low-level design issues, or implementation details that do not affect Nios II hardware or software designers.

Arithmetic Logic Unit

The Nios II/e core does not provide hardware support for any of the potential unimplemented instructions. All unimplemented instructions are emulated in software.

The Nios II/e core employs dedicated shift circuitry to perform shift and rotate operations. The dedicated shift circuitry achieves one-bit-per-cycle shift and rotate operations.

Memory Access

The Nios II/e core does not provide instruction cache or data cache. All memory and peripheral accesses generate an Avalon-MM transfer. The Nios II/e core can address up to 4 GB of external memory, full 32-bit addressing.

For information regarding data cache bypass methods, refer to the Processor Architecture chapter of the *Nios II Processor Reference Handbook*.

The Nios II/e core does not provide instruction cache or data cache. All memory and peripheral accesses generate an Avalon-MM transfer.

For information regarding data cache bypass methods, refer to the Processor Architecture chapter of the *Nios II Processor Reference Handbook*.

Processor Architecture on page 2-1

Instruction Execution Stages

This section provides an overview of the pipeline behavior as a means of estimating assembly execution time. Most application programmers never need to analyze the performance of individual instructions.

Instruction Performance

The Nios II/e core dispatches a single instruction at a time, and the processor waits for an instruction to complete before fetching and dispatching the next instruction. Because each instruction completes before the next instruction is dispatched, branch prediction is not necessary. This greatly simplifies the consideration of processor stalls. Maximum performance is one instruction per six clock cycles. To achieve six cycles, the Avalon-MM instruction master port must fetch an instruction in one clock cycle. A stall on the Avalon-MM instruction master port directly extends the execution time of the instruction.

Table 5-12: Instruction Execution Performance for Nios II/e Core

Instruction	Cycles
Normal ALU instructions (e.g., `add`, `cmplt`)	6
All branch, `jmp`, `jmpi`, `ret`, `call`, `callr`	6
`trap`, `break`, `eret`, `bret`, `flushp`, `wrctl`, `rdctl`, unimplemented	6
All load word	6 + Duration of Avalon-MM read transfer
All load halfword	9 + Duration of Avalon-MM read transfer
All load byte	10 + Duration of Avalon-MM read transfer
All store	6 + Duration of Avalon-MM write transfer
All shift, all rotate	7 to 38
All other instructions	6
Combinatorial custom instructions	6
Multicycle custom instructions	6

Exception Handling

The Nios II/e core supports the following exception types:

- Internal hardware interrupt
- Software trap
- Illegal instruction
- Unimplemented instruction

JTAG Debug Module

The Nios II/e core supports the JTAG debug module to provide a JTAG interface to software debugging tools. The JTAG debug module on the Nios II/e core does not support hardware breakpoints or trace.

Document Revision History

Table 5-13: Document Revision History

Date	Version	Changes

April 2015	2015.04.02	Initial release

NII51018   ✉ **Subscribe**   💬 **Send Feedback**

Each release of the Nios® II Embedded Design Suite (EDS) introduces improvements to the Nios II processor, the software development tools, or both. This chapter catalogs the history of revisions to the Nios II processor; it does not track revisions to development tools, such as the Nios II Software Build Tools (SBT).

Improvements to the Nios II processor might affect:

- Features of the Nios II architecture—An example of an architecture revision is adding instructions to support floating-point arithmetic.
- Implementation of a specific Nios II core—An example of a core revision is increasing the maximum possible size of the data cache memory for the Nios II/f core.
- Features of the JTAG debug module—An example of a JTAG debug module revision is adding an additional trigger input to the JTAG debug module, allowing it to halt processor execution on a new type of trigger event.

Altera implements Nios II revisions such that code written for an existing Nios II core also works on future revisions of the same core.

Nios II Versions

The number for any version of the Nios II processor is determined by the version of the Nios II EDS.

Table 6-1: Document Revision History

Version	Release Date	Notes
14.0	January 2015	Initial release of the Nios II Gen2 processor.

Architecture Revisions

Architecture revisions augment the fundamental capabilities of the Nios II architecture, and affect all Nios II cores. A change in the architecture mandates a revision to all Nios II cores to accommodate the new architectural enhancement. For example, when Altera adds a new instruction to the instruction set, Altera consequently must update all Nios II cores to recognize the new instruction.

ALTERA
now part of Intel

Table 6-2: Nios II Architecture Revisions

Version	Release Date	Notes
14.0	January 2015	Initial release of the Nios II Gen2 processor architecture.

Core Revisions

Core revisions introduce changes to an existing Nios II core. Core revisions most commonly fix identified bugs, or add support for an architecture revision. Not every Nios II core is revised with every release of the Nios II architecture.

Nios II/f Core

This chapter describes the Application Binary Interface (ABI) for the Nios® II processor. The ABI describes:

- How data is arranged in memory
- Behavior and structure of the stack
- Function calling conventions

Data Types

Table 7-1: Representation of Data C/C++ Types

Type	Size (Bytes)	Representation
char, signed char	1	two's complement (ASCII)
unsigned char	1	binary (ASCII)
short, signed short	2	two's complement
unsigned short	2	binary
int, signed int	4	two's complement
unsigned int	4	binary
long, signed long	4	two's complement
unsigned long	4	binary
float	4	IEEE
double	8	IEEE
pointer	4	binary
long long	8	two's complement
unsigned long long	8	binary

Memory Alignment

Contents in memory are aligned as follows:

- A function must be aligned to a minimum of 32-bit boundary.
- The minimum alignment of a data element is its natural size. A data element larger than 32 bits need only be aligned to a 32-bit boundary.
- Structures, unions, and strings must be aligned to a minimum of 32 bits.
- Bit fields inside structures are always 32-bit aligned.

Register Usage

The ABI adds additional usage conventions to the Nios II register file defined in the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Table 7-2: Nios II ABI Register Usage

Register	Name	Used by Compiler	Callee Saved[42]	Normal Usage
r0	zero	v		0x00000000
r1	at			Assembler temporary
r2		v		Return value (least-significant 32 bits)
r3		v		Return value (most-significant 32 bits)
r4		v		Register arguments (first 32 bits)
r5		v		Register arguments (second 32 bits)
r6		v		Register arguments (third 32 bits)
r7		v		Register arguments (fourth 32 bits)
r8		v		Caller-saved general-purpose registers
r9		v		
r10		v		
r11		v		
r12		v		
r13		v		
r14		v		
r15		v		

[42] A function can use one of these registers if it saves it first. The function must restore the register's original value before exiting.

Register	Name	Used by Compiler	Callee Saved[42]	Normal Usage
r16		v	v	Callee-saved general-purpose registers
r17		v	v	
r18		v	v	
r19		v	v	
r20		v	v	
r21		v	v	
r22		v	[43]	
r23		v	[44]	
r24	et			Exception temporary
r25	bt			Break temporary
r26	gp	v		Global pointer
r27	sp	v		Stack pointer
r28	fp	v	[45]	Frame pointer
r29	ea			Exception return address
r30	ba			• Normal register set: Break return address • Shadow register sets: SSTATUS register
r31	ra	v		Return address

The endianness of values greater than 8 bits is little endian. The upper 8 bits of a value are stored at the higher byte address.

Related Information

- **Frame Pointer Elimination** on page 7-4
- **Programming Model** on page 3-1

Stacks

The stack grows downward (i.e. towards lower addresses). The stack pointer points to the last used slot. The frame pointer points to the saved frame pointer near the top of the stack frame.

---

[42] A function can use one of these registers if it saves it first. The function must restore the register's original value before exiting.

[43] In the GNU Linux operating system, r22 points to the global offset table (GOT). Otherwise, it is available as a callee-saved general-purpose register.

[44] In the GNU Linux operating system, r23 is used as the thread pointer. Otherwise, it is available as a callee-saved general-purpose register.

[45] If the frame pointer is not used, the register is available as a callee-saved temporary register. Refer to "Frame Pointer Elimination".

The figure below shows an example of the structure of a current frame. In this case, function `a()` calls function `b()`, and the stack is shown before the call and after the prologue in the called function has completed.

Figure 7-1: Stack Pointer, Frame Pointer and the Current Frame
Each section of the current frame is aligned to a 32-bit boundary. The ABI requires the stack pointer be 32-bit aligned at all times.

Frame Pointer Elimination

The frame pointer is provided for debugger support. If you are not using a debugger, you can optimize your code by eliminating the frame pointer, using the `-fomit-frame-pointer` compiler option. When the frame pointer is eliminated, register `fp` is available as a temporary register.

Call Saved Registers

The compiler is responsible for generating code to save registers that need to be saved on entry to a function, and to restore the registers on exit. If there are any such registers, they are saved on the stack, from high to low addresses, in the following order: `ra`, `fp`, `sp`, `gp`, `r25`, `r24`, `r23`, `r22`, `r21`, `r20`, `r19`, `r18`, `r17`, `r16`, `r15`, `r14`, `r13`, `r12`, `r11`, `r10`, `r9`, `r8`, `r7`, `r6`, `r5`, `r4`, `r3`, and `r2`. Stack space is not allocated for registers that are not saved.

Further Examples of Stacks

There are a number of special cases for stack layout, which are described in this section.

Stack Frame for a Function With alloca()

The Nios II stack frame implementation provides support for the `alloca()` function, defined in the Berkeley Software Distribution (BSD) extension to C, and implemented by the gcc compiler. The space allocated by `alloca()` replaces the outgoing arguments and the outgoing arguments get new space allocated at the bottom of the frame.

Note: The Nios II C/C++ compiler maintains a frame pointer for any function that calls `alloca()`, even if `-fomit-frame-pointer` is spec if ed

Figure 7-2: Stack Frame after Calling alloca()
Stack Frame for a Function with Variable Arguments

Functions that take variable arguments (`varargs`) still have their first 16 bytes of arguments arriving in registers `r4` through `r7`, just like other functions.

In order for `varargs` to work, functions that take variable arguments allocate 16 extra bytes of storage on the stack. They copy to the stack the first 16 bytes of their arguments from registers `r4` through `r7` as shown below.

Figure 7-3: Stack Frame Using Variable Arguments
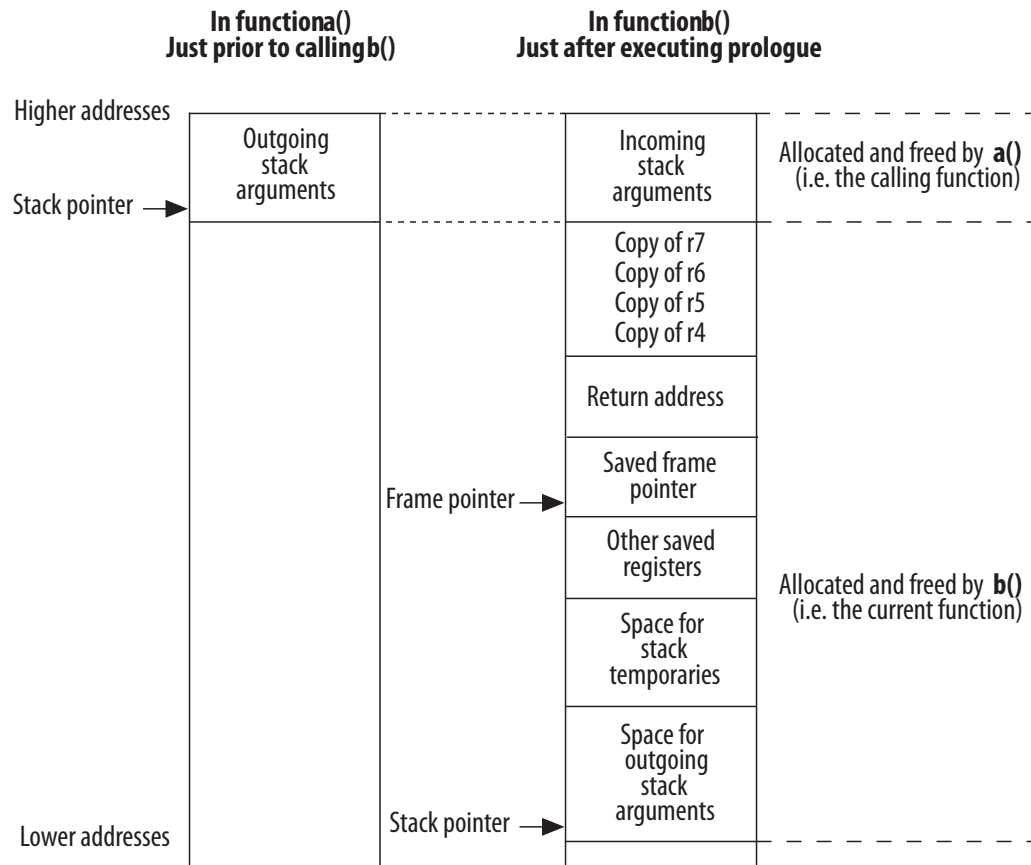

Stack Frame for a Function with Structures Passed By Value

Functions that take `struct` value arguments still have their first 16 bytes of arguments arriving in registers `r4` through `r7`, just like other functions.

If part of a structure is passed using registers, the function might need to copy the register contents back to the stack. This operation is similar to that required in the variable arguments case as shown in the figure above, *Stack Frame Using Variable Arguments*.

Related Information

Stack Frame for a Function with Variable Arguments on page 7-5

Function Prologues

The Nios II C/C++ compiler generates function prologues that allocate the stack frame of a function for storage of stack temporaries and outgoing arguments. In addition, each prologue is responsible for saving the state of the calling function. This entails saving certain registers on the stack. These registers, the callee-saved registers, are listed in Nios II ABI Register Usage Table in the Register Usage section. A function prologue is required to save a callee-saved register only if the function uses the register.

Given the function prologue algorithm, when doing a back trace, a debugger can disassemble instructions and reconstruct the processor state of the calling function.

Note: An even better way to find out what the prologue has done is to use information stored in the DWARF-2 debugging fields of the executable and linkable format (**.elf**) file.

The instructions found in a Nios II function prologue perform the following tasks:

- Adjust the stack pointer (to allocate the frame)
- Store registers to the frame
- Set the frame pointer to the location of the saved frame pointer

Example 7-1: A function prologue

```
/* Adjust the stack pointer */
addi    sp, sp, -16   /* make a 16-byte frame */

/* Store registers to the frame */
stw     ra, 12(sp)    /* store the return address */
stw     fp, 8(sp)     /* store the frame pointer*/
stw     r16, 4(sp)    /* store callee-saved register */
stw     r17, 0(sp)    /* store callee-saved register */

/* Set the new frame pointer */
addi    fp, sp, 8
```

Related Information

Prologue Variations

The following variations can occur in a prologue:

- If the function's frame size is greater than 32,767 bytes, extra temporary registers are used in the calculation of the new stack pointer as well as for the offsets of where to store callee-saved registers. The extra registers are needed because of the maximum size of immediate values allowed by the Nios II processor.
- If the frame pointer is not in use, the final instruction, recalculating the frame pointer, is not generated.
- If variable arguments are used, extra instructions store the argument registers on the stack.
- If the compiler designates the function as a leaf function, the return address is not saved.
- If optimizations are on, especially instruction scheduling, the order of the instructions might change and become interlaced with instructions located after the prologue.

Arguments and Return Values

This section discusses the details of passing arguments to functions and returning values from functions.

Arguments

The first 16 bytes to a function are passed in registers `r4` through `r7`. The arguments are passed as if a structure containing the types of the arguments were constructed, and the first 16 bytes of the structure are located in `r4` through `r7`.

A simple example:

```
int function (int a, int b);
```

The equivalent structure representing the arguments is:

```
struct { int a; int b; };
```

The first 16 bytes of the `struct` are assigned to `r4` through `r7`. Therefore `r4` is assigned the value of a and `r5` the value of b.

The first 16 bytes to a function taking variable arguments are passed the same way as a function not taking variable arguments. The called function must clean up the stack as necessary to support the variable arguments.

Refer to Stack Frame for a Function with Variable Arguments

Related Information
Stack Frame for a Function with Variable Arguments on page 7-5

Return Values

Return values of types up to 8 bytes are returned in `r2` and `r3`. For return values greater than 8 bytes, the caller must allocate memory for the result and must pass the address of the result memory as a hidden zero argument.

The hidden zero argument is best explained through an example.

Example 7-2: Returned struct

```
/* b() computes a structure-type result and returns it */
STRUCT b(int i, int j)
{
    ...
    return result;
}
void a(...)
{
    ...
    value = b(i, j);
}
```

In the example above, if the result type is no larger than 8 bytes, `b()` returns its result in `r2` and `r3`.

If the return type is larger than 8 bytes, the Nios II C/C++ compiler treats this program as if `a()` had passed a pointer to `b()`. The example below shows how the Nios II C/C++ compiler sees the code in the Returned Struct example above.

Example 7-3: Returned struct is Larger than 8 Bytes

```
void b(STRUCT *p_result, int i, int j)
{
    ...
    *p_result = result;
}

void a(...)
{
    STRUCT value;
    ...
```

```
        b(&value, i, j);
    }
```

DWARF-2 Definition

Registers `r0` through `r31` are assigned numbers 0 through 31 in all DWARF-2 debugging sections.

Object Files

Table 7-3: Nios II-Specific ELF Header Values

Member	Value
`e_ident[EI_CLASS]`	ELFCLASS32
`e_ident[EI_DATA]`	ELFDATA2LSB
`e_machine`	EM_ALTERA_NIOS2 == 113

Relocation

In a Nios II object file, each relocatable address reference possesses a relocation type. The relocation type specifies how to calculate the relocated address. The bit mask specifies where the address is found in the instruction.

Table 7-4: Nios II Relocation Calculation

Name	Value	Overflow check [46]	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_NONE	0	n/a	None	n/a	n/a
R_NIOS2_S16	1	Yes	S + A	0x003FFFC0	6
R_NIOS2_U16	2	Yes	S + A	0x003FFFC0	6
R_NIOS2_PCREL16	3	Yes	((S + A) – 4) – PC	0x003FFFC0	6
R_NIOS2_CALL26[47]	4	Yes	(S + A) >> 2	0xFFFFFFC0	6
R_NIOS2_CALL26_NOAT	41	No	(S + A) >> 2	0xFFFFFFC0	6
R_NIOS2_IMM5	5	Yes	(S + A) & 0x1F	0x000007C0	6
R_NIOS2_CACHE_OPX	6	Yes	(S + A) & 0x1F	0x07C00000	22

---

[46] For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.

[47] Linker is permitted to clobber register AT in the course of resolving overflows

---

[46] For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.

Name	Value	Overflow check (46)	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_CALL_LO	44[48]	No	G & 0xFFFF	0x003FFFC0	6
R_NIOS2_CALL_HA	45[48]	No	Adj(G)	0x003FFFC0	6

Expressions in the table above use the following conventions:

- S: Symbol address
- A: Addend
- PC: Program counter
- GP: Global pointer
- Adj(X): (((X >> 16) & 0xFFFF) + ((X >> 15) & 0x1)) & 0xFFFF
- BA: The base address at which a shared library is loaded
- GOT: The value of the Global Offset Table (GOT) pointer (Linux only)
- G: The offset into the GOT for the GOT slot for symbol S (Linux only)

With the information in the table above, any Nios II instruction can be relocated by manipulating it as an unsigned 32-bit integer, as follows:

Xr = ((R << B) & M | (X & ~M));

where:

- R is the relocated address, calculated in the above table
- B is the bit shift
- M is the bit mask
- X is the original instruction
- Xr is the relocated instruction

Linux Toolchain Relocation Information

Dynamic relocations can appear in the runtime relocation sections of executables and shared objects, but never appear in object files (with the exception of R_NIOS2_TLS_DTPREL, which is used for debug information). No other relocations are dynamic.

Table 7-5: Dynamic Relocations

R_NIOS2_TLS_DTPMOD
R_NIOS2_TLS_DTPREL
R_NIOS2_TLS_TPREL
R_NIOS2_COPY
R_NIOS2_GLOB_DAT
R_NIOS2_JUMP_SLOT
R_NIOS2_RELATIVE

A global offset table (GOT) entry referenced using R_NIOS2_GOT16, R_NIOS2_GOT_LO and/or R_NIOS2_GOT_HA must be resolved at load time. A GOT entry referenced only using R_NIOS2_CALL16, R_NIOS2_CALL_LO and/or R_NIOS2_CALL_HA can initially refer to a procedure linkage table (PLT) entry and then be resolved lazily.

Because the TP-relative relocations are 16-bit relocations, no dynamic object using local dynamic or local executable thread-local storage (TLS) can have more than 64 KB of TLS data. New relocations might be added to support this in the future.

Several new assembler operators are defined to generate the Linux-specific relocations, as listed in the table below.

Table 7-6: Relocation and Operator

Relocation	Operator
R_NIOS2_GOT16	`%got`
R_NIOS2_CALL16	`%call`
R_NIOS2_GOTOFF_LO	`%gotoff_hiadj`
R_NIOS2_GOTOFF_HA	`%gotoff_lo`
R_NIOS2_PCREL_LO	`%hiadj`
R_NIOS2_PCREL_HA	`%lo`
R_NIOS2_TLS_GD16	`%tls_gd`
R_NIOS2_TLS_LDM16	`%tls_ldm`
R_NIOS2_TLS_LDO16	`%tls_ldo`
R_NIOS2_TLS_IE16	`%tls_ie`
R_NIOS2_TLS_LE16	`%tls_le`

Relocation	Operator
R_NIOS2_TLS_DTPREL	`%tls_ldo`
R_NIOS2_GOTOFF	`%gotoff`
R_NIOS2_GOT_LO	`%got_lo`
R_NIOS2_GOT_HA	`%got_hiadj`
R_NIOS2_CALL_LO	`%call_lo`
R_NIOS2_CALL_HA	`%call_hiadj`

The `%hiadj` and `%lo` operators generate PC-relative or non-PC-relative relocations, depending whether the expression being relocated is PC-relative. For instance, `%hiadj(_gp_got - .)` generates R_NIOS2_PCREL_HA. `%tls_ldo` generates R_NIOS2_TLS_LDO16 when used as an immediate operand, and R_NIOS2_TLS_DTPREL when used with the `.word` directive.

Copy Relocation

The R_NIOS2_COPY relocation is used to mark variables allocated in the executable that are defined in a shared library. The variable's initial value is copied from the shared library to the relocated location.

Jump Slot Relocation

Jump slot relocations are used for the PLT.

For information about the PLT, refer to "Procedure Linkage Table" section.

Thread-Local Storage

The Nios II processor uses the Variant I model for thread-local storage.

The end of the thread control block (TCB) is located 0x7000 bytes before the thread pointer. The TCB is eight bytes long. The first word is the dynamic thread pointer (DTV) pointer and the second word is reserved. Each module's dynamic thread pointer is biased by 0x8000 (when retrieved using `__tls_get_addr`). The thread library can store additional private information before the TCB.

In the GNU Linux toolchain, the GOT pointer (`_gp_got`) is always kept in `r22`, and the thread pointer is always kept in `r23`.

In the following examples, any registers can be used, except that the argument to `__tls_get_addr` is always passed in `r4` and its return value is always returned in `r2`. Calls to `__tls_get_addr` must use the normal position-independent code (PIC) calling convention in PIC code; these sequences are for example only, and the compiler might generate different sequences. No linker relaxations are defined.

Example 7-4: General Dynamic Model

```
addi r4, r22, %tls_gd(x)        # R_NIOS2_TLS_GD16 x
call __tls_get_addr             # R_NIOS2_CALL26 __tls_get_addr
# Address of x in r2
```

In the general dynamic model, a two-word GOT slot is allocated for x, as shown in "GOT Slot for General Dynamic Model" example.

Example 7-5: GOT Slot for General Dynamic Model

```
GOT[n]                  R_NIOS2_TLS_DTPMOD x
GOT[n+1]                R_NIOS2_TLS_DTPREL x
```

Example 7-6: Local Dynamic Model

```
addi r4, r22, %tls_ldm(x)              # R_NIOS2_TLS_LDM16 x
call __tls_get_addr                    # R_NIOS2_CALL26 __tls_get_addr
addi r5, r2, %tls_ldo(x)               # R_NIOS2_TLS_LDO16 x
# Address of x in r5
ldw r6, %tls_ldo(x2)(r2)               # R_NIOS2_TLS_LDO16 x2
# Value of x2 in r6
```

One 2-word GOT slot is allocated for all R_NIOS2_TLS_LDM16 operations in the linked object. Any thread-local symbol in this object can be used, as shown in "GOT Slot with Thread-Local Storage" example.

Example 7-7: GOT Slot with Thread-Local Storage

```
GOT[n]           R_NIOS2_TLS_DTPMOD x
GOT[n+1]         0
```

Example 7-8: Initial Exec Model

```
ldw      r4, %tls_ie(x)(r22)        # R_NIOS2_TLS_IE16 x
add      r4, r23, r4
# Address of x in r4
```

A single GOT slot is allocated to hold the offset of x from the thread pointer, as shown in "GOT SLot for Initial Exec Model" example.

Example 7-9: GOT Slot for Initial Exec Model

```
GOT[n]           R_NIOS2_TLS_TPREL x
```

Example 7-10: Local Exec Model

```
addi        r4, r23, %tls_le(x)         # R_NIOS2_TLS_LE16 x
# Address of x in r4
```

There is no GOT slot associated with the local exec model.

Debug information uses the GNU extension DW_OP_GNU_push_tls_address.

Example 7-11: Debug Information

```
.byte 0x03                  # DW_OP_addr
.word %tls_ldo(x)           # R_NIOS2_TLS_DTPREL x
.byte 0xe0                  # DW_OP_GNU_push_tls_address
```

Linux Function Calls

Register `r23` is reserved for the thread pointer on GNU Linux systems. It is initialized by the C library and it may be used directly for TLS access, but not modified. On non-Linux systems `r23` is a general-purpose, callee-saved register.

The global pointer, `r26` or `gp`, is globally fixed. It is initialized in startup code and always valid on entry to a function. This method does not allow for multiple `gp` values, so `gp`-relative data references are only possible in the main application (that is, from position dependent code). `gp` is only used for small data access, not GOT access, because code compiled as PIC may be used from shared libraries. The linker may take advantage of `gp` for shorter PLT sequences when the addresses are in range. The compiler needs an option to disable use of `gprel`; the option is necessary for applications with excessive amounts of small data. For comparison, XUL (Mozilla display engine, 16 MB code, 2 MB data) has only 27 KB of small data and the limit is 64 KB. This option is separate from -G 0, because -G 0 creates ABI incompatibility. A file compiled with -G 0 puts global `int` variables into `.data` but files compiled with -G 8 expect such `int` variables to be in `.sdata`.

PIC code which needs a GOT pointer needs to initialize the pointer locally using `nextpc`; the GOT pointer is not passed during function calls. This approach is compatible with both static relocatable binaries and System V style shared objects. A separate ABI is needed for shared objects with independently relocatable text and data.

Stack alignment is 32-bit. The frame pointer points at the top of the stack when it is in use, to simplify backtracing. Insert `alloca` between the local variables and the outgoing arguments. The stack pointer points to the bottom of the outgoing argument area.

A large `struct` return value is handled by passing a pointer in the first argument register (not the disjoint return value register).

Linux Operating System Call Interface

Table 7-7: Signals for Unhandled Instruction-Related Exceptions

Exception	Signal
Supervisor-only instruction address	SIGSEGV

Exception	Signal
TLB permission violation (execute)	`SIGSEGV`
Supervisor-only instruction	`SIGILL`
Unimplemented instruction	`SIGILL`
Illegal instruction	`SIGILL`
Break instruction	`SIGTRAP`
Supervisor-only data address	`SIGSEGV`
Misaligned data address	`SIGBUS`
Misaligned destination address	`SIGBUS`
Division error	`SIGFPE`
TLB Permission Violation (read)	`SIGSEGV`
TLB Permission Violation (write)	`SIGSEGV`

There are no floating-point exceptions. The optional floating point unit (FPU) does not support exceptions and any process wanting exact IEEE conformance needs to use a soft-float library (possibly accelerated by use of the attached FPU).

The `break` instruction in a user process might generate a `SIGTRAP` signal for that process, but is not required to. Userspace programs should not use the `break` instruction and userspace debuggers should not insert one. If no hardware debugger is connected, the OS should assure that the `break` instruction does not cause the system to stop responding.

For information about userspace debugging, refer to "Userspace Breakpoints".

The page size is 4 KB. Virtual addresses in user mode are all below 2 GB due to the MMU design. The NULL page is not mapped.

Related Information

Userspace Breakpoints on page 7-23

Linux Process Initialization

The stack pointer, `sp`, points to the argument count on the stack.

Table 7-8: Stack Initial State at User Process Start

Purpose	Start Address	Length
Unspecified	High addresses	
Referenced strings		Varies
Unspecified		
Null auxilliary vector entry		4 bytes
Auxilliary vector entries		8 bytes each
NULL terminator for envp		4 bytes

Purpose	Start Address	Length
Environment pointers	sp + 8 + 4 × argc	4 bytes each
NULL terminator for argv	sp + 4 + 4 × argc	4 bytes
Argument pointers	sp + 4	4 bytes each
Argument count	sp	4 bytes
Unspecified	Low addresses	

If the application should register a destructor function with atexit, the pointer is placed in r4. Otherwise r4 is zero.

The contents of all other registers are unspecified. User code should set fp to zero to mark the end of the frame chain.

The auxiliary vector is a series of pairs of 32-bit tag and 32-bit value, terminated by an AT_NULL tag.

Linux Position-Independent Code

Every position-independent code (PIC) function which uses global data or global functions must load the value of the GOT pointer into a register. Any available register may be used. If a caller-saved register is used the function must save and restore it around calls. If a callee-saved register is used it must be saved and restored around the current function. Examples in this document use r22 for the GOT pointer.

The GOT pointer is loaded using a PC-relative offset to the _gp_got symbol, as shown below.

Example 7-12: Loading the GOT Pointer

```
nextpc r22
1:
    orhi r1, %hiadj(_gp_got - 1b) # R_NIOS2_PCREL_HA _gp_got
    addi r1, r1, %lo(_gp_got - 1b) # R_NIOS2_PCREL_LO _gp_got - 4
    add r22, r22, r1
    # GOT pointer in r22
```

Data may be accessed by loading its location from the GOT. A single word GOT entry is generated for each referenced symbol.

Example 7-13: Small GOT Model Entry for Global Symbols

```
addi    r3, r22, %got(x)       # R_NIOS2_GOT16

GOT[n]                         R_NIOS2_GLOB_DAT x
```

Example 7-14: Large GOT Model Entry for Global Symbols

```
movhi r3,     %got_hiadj(x)    # R_NIOS2_GOT_HA
addi  r3, r3, %got_lo(x)       # R_NIOS2_GOT_LO
add   r3, r3, r22
```

```
GOT[n]                                   R_NIOS2_GLOB_DAT x
```

For local symbols, the symbolic reference to *x* is replaced by a relative relocation against symbol zero, with the link time address of *x* as an addend, as shown in the example below.

Example 7-15: Local Symbols for small GOT Model

```
addi    r3, r22, %got(x)           # R_NIOS2_GOT16

GOT[n]                                 R_NIOS2_RELATIVE +x
```

Example 7-16: Local Symbols for large GOT Model

```
movhi r3,      %got_hiadj(x)       # R_NIOS2_GOT_HA
addi  r3, r3, %got_lo(x)           # R_NIOS2_GOT_LO
add   r3, r3, r22

GOT[n]                                 R_NIOS2_RELATIVE +x
```

The `call` and `jmpi` instructions are not available in position-independent code. Instead, all calls are made through the GOT. Function addresses may be loaded with `%call`, which allows lazy binding. To initialize a function pointer, load the address of the function with `%got` instead. If no input object requires the address of the function its GOT entry is placed in the PLT GOT for lazy binding, as shown in the example below.

For information about the PLT, refer to the "Procedure Linkage Table" section.

Example 7-17: Small GOT Model entry in PLT GOT

```
ldw     r3, %call(fun)(r22)        # R_NIOS2_CALL16 fun
callr   r3

PLTGOT[n]                              R_NIOS_JUMP_SLOT fun
```

Example 7-18: Large GOT Model entry in PLT GOT

```
movhi r3,      %call_hiadj(x)      # R_NIOS2_CALL_HA
addi  r3, r3, %call_lo(x)          # R_NIOS2_CALL_LO
add   r3, r3, r22
ldw   r3, 0(r3)
callr r3

PLTGOT[n]                              R_NIOS_JUMP_SLOT fun
```

When a function or variable resides in the current shared object at compile time, it can be accessed via a PC-relative or GOT-relative offset, as shown below.

Example 7-19: Accessing Function or Variable in Current Shared Object

```
orhi      r3, %gotoff_hiadj(x)        # R_NIOS2_GOTOFF_HA x
addi      r3, r3, %gotoff_lo(x)       # R_NIOS2_GOTOFF_LO x
add       r3, r22, r3
# Address of x in r3
```

Multiway branches such as switch statements can be implemented with a table of GOT-relative offsets, as shown below.

Example 7-20: Switch Statement Implemented with Table

```
# Scaled table offset in r4
    orhi      r3, %gotoff_hiadj(Ltable)     # R_NIOS2_GOTOFF_HA Ltable
    addi      r3, r3, %gotoff_lo(Ltable)    # R_NIOS2_GOTOFF_LO Ltable
    add       r3, r22, r3                   # r3 == &Ltable
    add       r3, r3, r4
    ldw       r4, 0(r3)                     # r3 == Ltable[index]
    add       r4, r4, r22                   # Convert offset into destina-
tion
    jmp       r4
    ...
Ltable:
    .word %gotoff(Label1)
    .word %gotoff(Label2)
    .word %gotoff(Label3)
```

Related Information

[Procedure Linkage Table](#) on page 7-21

Linux Program Loading and Dynamic Linking

Global Offset Table

Because shared libraries are position-independent, they can not contain absolute addresses for symbols. Instead, addresses are loaded from the GOT.

The first word of the GOT is filled in by the link editor with the unrelocated address of the _DYNAMIC, which is at the start of the dynamic section. The second and third words are reserved for the dynamic linker.

For information about the dynamic linker, refer to the "Procedure Linkage Table" section.

The linker-defined symbol _GLOBAL_OFFSET_TABLE_ points to the reserved entries at the beginning of the GOT. The linker-defined symbol _gp_got points to the base address used for GOT-relative relocations. The value of _gp_got might vary between object files if the linker creates multiple GOT sections.

Related Information

[Procedure Linkage Table](#) on page 7-21

Function Addresses

Function addresses use the same `SHN_UNDEF` and `st_value` convention for PLT entries as in other architectures, such as x86_64.

Procedure Linkage Table

Function calls in a position-dependent executable may use the `call` and `jmpi` instructions, which address the contents of a 256-MB segment. They may also use the `%lo`, `%hi`, and `%hiadj` operators to take the address of a function. If the function is in another shared object, the link editor creates a callable stub in the executable called a PLT entry. The PLT entry loads the address of the called function from the PLT GOT (a region at the start of the GOT) and transfers control to it.

The PLT GOT entry needs a relocation referring to the final symbol, of type R_NIOS2_JUMP_SLOT. The dynamic linker may immediately resolve it, or may leave it unmodified for lazy binding. The link editor fills in an initial value pointing to the lazy binding stubs at the start of the PLT section.

Each PLT entry appears as shown in the example below.

Example 7-21: PLT Entry

```
.PLTn:
    orhi   r15, r0, %hiadj(plt_got_slot_address)
    ldw    r15, %lo(plt_got_slot_address)(r15)
    jmp    r15
```

The example below shows the PLT entry when the PLT GOT is close enough to the small data area for a relative jump.

Example 7-22: PLT Entry Near Small Data Area

```
.PLTn:
    ldw    r15, %gprel(plt_got_slot_address)(gp)
    jmp    r15
```

Example 7-23: Initial PLT Entry

```
res_0:
    br .PLTresolve
    ...
.PLTresolve:
    orhi    r14, r0, %hiadj(res_0)
    addi    r14, r14, %lo(res_0)
    sub     r15, r15, r14
    orhi    r13, %hiadj(_GLOBAL_OFFSET_TABLE_)
    ldw     r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
    ldw     r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
    jmp     r13
```

In front of the initial PLT entry, a series of branches start of the initial entry (the `nextpc` instruction). There is one branch for each PLT entry, labelled res_0 through res_N. The last several branches may be

replaced by `nop` instructions to improve performance. The link editor arranges for the Nth PLT entry to point to the Nth branch; res_N – res_0 is four times the index into the `.rela.plt` section for the corresponding R_JUMP_SLOT relocation.

The dynamic linker initializes GOT[1] to a unique identifier for each library and GOT[2] to the address of the runtime resolver routine. In order for the two loads in `.PLTresolve` to share the same `%hiadj`, `_GLOBAL_OFFSET_TABLE_` must be aligned to a 16-byte boundary.

The runtime resolver receives the original function arguments in `r4` through `r7`, the shared library identifier from GOT[1] in `r14`, and the relocation index times four in `r15`. The resolver updates the corresponding PLT GOT entry so that the PLT entry transfers control directly to the target in the future, and then transfers control to the target.

In shared objects, the `call` and `jmpi` instructions can not be used because the library load address is not known at link time. Calls to functions outside the current shared object must pass through the GOT. The program loads function addresses using `%call`, and the link editor may arrange for such entries to be lazily bound. Because PLT entries are only used for lazy binding, shared object PLTs are smaller, as shown below.

Example 7-24: Shared Object PLT

```
.PLTn:
    orhi    r15, r0, %hiadj(index * 4)
    addi    r15, r15, %lo(index * 4)
    br      .PLTresolve
```

Example 7-25: Initial PLT Entry

```
.PLTresolve:
    nextpc  r14
    orhi    r13, r0, %hiadj(_GLOBAL_OFFSET_TABLE_)
    add     r13, r13, r14
    ldw     r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
    ldw     r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
    jmp     r13
```

If the initial PLT entry is out of range, the resolver can be inline, because it is only one instruction longer than a long branch, as shown below.

Example 7-26: Initial PLT Entry Out of Range

```
.PLTn:
    orhi    r15, r0, %hiadj(index * 4)
    addi    r15, r15, %lo(index * 4)
    nextpc  r14
    orhi    r13, r0, %hiadj(_GLOBAL_OFFSET_TABLE_)
    add     r13, r13, r14
    ldw     r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
    ldw     r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
    jmp     r13
```

Linux Program Interpreter

The program interpreter is **/lib/ld.so.1**.

Linux Initialization and Termination Functions

The implementation is responsible for calling `DT_INIT()`, `DT_INIT_ARRAY()`, `DT_PREINIT_ARRAY()`, `DT_FINI()`, and `DT_FINI_ARRAY()`.

Linux Conventions

System Calls

The Linux system call interface relies on the `trap` instruction with immediate argument zero. The system call number is passed in register `r2`. The arguments are passed in `r4`, `r5`, `r6`, `r7`, `r8`, and `r9` as necessary. The return value is written in `r2` on success, or a positive error number is written to `r2` on failure. A flag indicating successful completion, to distinguish error values from valid results, is written to `r7`; 0 indicates `syscall` success and 1 indicates `r2` contains a positive `errno` value.

Userspace Breakpoints

Userspace breakpoints are accomplished using the `trap` instruction with immediate operand 31 (all ones). The OS must distinguish this instruction from a `trap 0` system call and generate a `trap` signal.

Atomic Operations

The Nios II architecture does not have atomic operations (such as load linked and store conditional). Atomic operations are emulated using a kernel system call via the `trap` instruction. The toolchain provides intrinsic functions which perform the system call. Applications must use those functions rather than the system call directly. Atomic operations may be added in a future processor extension.

Processor Requirements

Linux requires that a hardware multiplier be present. The full 64-bit multiplier (`mulx` instructions) is not required.

Development Environment

The following symbols are defined:

- `__nios2`
- `__nios2__`
- `__NIOS2`
- `__NIOS2__`

Document Revision History

Table 7-9: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
April 2015	2015.04.02	Initial release

This section introduces the Nios® II instruction word format and provides a detailed reference of the Nios II instruction set.

Word Formats

There are three types of Nios II instruction word format: I-type, R-type, and J-type.

I-Type

The defining characteristic of the I-type instruction word format is that it contains an immediate value embedded within the instruction word. I-type instructions words contain:

- A 6-bit opcode field OP
- Two 5-bit register fields A and B
- A 16-bit immediate data field IMM16

In most cases, fields A and IMM16 specify the source operands, and field B specifies the destination register. IMM16 is considered signed except for logical operations and unsigned comparisons.

I-type instructions include arithmetic and logical operations such as `addi` and `andi`; branch operations; load and store operations; and cache management operations.

Table 8-1: I-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										OP					

R-Type

The defining characteristic of the R-type instruction word format is that all arguments and results are specified as registers. R-type instructions contain:

now part of Intel

- A 6-bit opcode field OP
- Three 5-bit register fields A, B, and C
- An 11-bit opcode-extension field OPX

In most cases, fields A and B specify the source operands, and field C specifies the destination register.

Some R-Type instructions embed a small immediate value in the five low-order bits of OPX. Unused bits in OPX are always 0.

R-type instructions include arithmetic and logical operations such as `add` and `nor`; comparison operations such as `cmpeq` and `cmplt`; the `custom` instruction; and other operations that need only register operands.

Table 8-2: R-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					OPX
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPX										OP					

J-Type

J-type instructions contain:

- A 6-bit opcode field
- A 26-bit immediate data field

J-type instructions, such as `call` and `jmpi`, transfer execution anywhere within a 256-MB range.

Table 8-3: J-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IMM26															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM26										OP					

Instruction Opcodes

The OP field in the Nios II instruction word specifies the major class of an opcode as listed in the two tables below. Most values of OP are encodings for I-type instructions. One encoding, OP = 0x00, is the J-type instruction `call`. Another encoding, OP = 0x3a, is used for all R-type instructions, in which case, the OPX field differentiates the instructions. All undefined encodings of OP and OPX are reserved.

Table 8-4: OP Encodings

OP	Instruction	OP	Instruction	OP	Instruction	OP	Instruction
0x00	call	0x10	cmplti	0x20	cmpeqi	0x30	cmpltui

Assembler Pseudo-Instructions

Pseudo-instructions are used in assembly source code like regular assembly instructions. Each pseudo-instruction is implemented at the machine level using an equivalent instruction. The `movia` pseudo-instruction is the only exception, being implemented with two instructions. Most pseudo-instructions do not appear in disassembly views of machine code.

Table 8-6: Assembler Pseudo-Instructions

Pseudo-Instruction	Equivalent Instruction
bgt rA, rB, label	blt rB, rA, label
bgtu rA, rB, label	bltu rB, rA, label
ble rA, rB, label	bge rB, rA, label
bleu rA, rB, label	bgeu rB, rA, label
cmpgt rC, rA, rB	cmplt rC, rB, rA
cmpgti rB, rA, IMMED	cmpgei rB, rA, (IMMED+1)
cmpgtu rC, rA, rB	cmpltu rC, rB, rA
cmpgtui rB, rA, IMMED	cmpgeui rB, rA, (IMMED+1)
cmple rC, rA, rB	cmpge rC, rB, rA
cmplei rB, rA, IMMED	cmplti rB, rA, (IMMED+1)
cmpleu rC, rA, rB	cmpgeu rC, rB, rA
cmpleui rB, rA, IMMED	cmpltui rB, rA, (IMMED+1)
mov rC, rA	add rC, rA, r0
movhi rB, IMMED	orhi rB, r0, IMMED
movi rB, IMMED	addi, rB, r0, IMMED
movia rB, label	orhi rB, r0, %hiadj(label)
	addi, rB, r0, %lo(label)
movui rB, IMMED	ori rB, r0, IMMED
nop	add r0, r0, r0
subi rB, rA, IMMED	addi rB, rA, (-IMMED)

Refer to the *Application Binary Interface* chapter of the *Nios II Processor Reference Handbook* for more information about global pointers.

Application Binary Interface on page 7-1

Assembler Macros

The Nios II assembler provides macros to extract halfwords from labels and from 32-bit immediate values. These macros return 16-bit signed values or 16-bit unsigned values depending on where they are used. When used with an instruction that requires a 16-bit signed immediate value, these macros return a value ranging from –32768 to 32767. When used with an instruction that requires a 16-bit unsigned immediate value, these macros return a value ranging from 0 to 65535.

Table 8-7: Assembler Macros

Macro	Description	Operation
`%lo(immed32)`	Extract bits [15..0] of immed32	immed32 & 0xFFFF
`%hi(immed32)`	Extract bits [31..16] of immed32	(immed32 >> 16) & 0xFFFF
`%hiadj(immed32)`	Extract bits [31..16] and adds bit 15 of immed32	((immed32 >> 16) & 0xFFFF) + ((immed32 >> 15) & 0x1)
`%gprel(immed32)`	Replace the immed32 address with an offset from the global pointer	immed32 –_gp

Refer to the *Application Binary Interface* chapter of the *Nios II Processor Reference Handbook* for more information about global pointers.

Application Binary Interface on page 7-1

Instruction Set Reference

The following pages list all Nios II instruction mnemonics in alphabetical order.

Table 8-8: Notation Conventions

Notation	Meaning
X ← Y	X is written with Y
PC ← X	The program counter (PC) is written with address X; the instruction at X is the next instruction to execute
PC	The address of the assembly instruction in question
rA, rB, rC	One of the 32-bit general-purpose registers
prs.rA	General-purpose register rA in the previous register set
IMMn	An n-bit immediate value, embedded in the instruction word
IMMED	An immediate value

Notation	Meaning
X_n	The nth bit of X, where n = 0 is the LSB
$X_{n..m}$	Consecutive bits n through m of X
0xNNMM	Hexadecimal notation
X : Y	Bitwise concatenation For example, (0x12 : 0x34) = 0x1234
σ(X)	The value of X after being sign-extended to a full register-sized signed integer
X >> n	The value X after being right-shifted n bit positions
X << n	The value X after being left-shifted n bit positions
X & Y	Bitwise logical AND
X | Y	Bitwise logical OR
X ^ Y	Bitwise logical XOR
~X	Bitwise logical NOT (one's complement)
Mem8[X]	The byte located in data memory at byte address X
Mem16[X]	The halfword located in data memory at byte address X
Mem32[X]	The word located in data memory at byte address X
label	An address label specified in the assembly file
(signed) rX	The value of rX treated as a signed number
(unsigned) rX	The value of rX treated as an unsigned number

Note: All register operations apply to the current register set, except as noted.

The following exceptions are not listed for each instruction because they can occur on any instruction fetch:

- Supervisor-only instruction address
- Fast TLB miss (instruction)
- Double TLB miss (instruction)
- TLB permission violation (execute)
- MPU region violation (instruction)

For information about these and all Nios II exceptions, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Programming Model on page 3-1

add

Instruction	add
Operation	rC ← rA + rB

Assembler Syntax	add rC, rA, rB
Example	add r6, r7, r8
Description	Calculates the sum of rA and rB. Stores the result in rC. Used for both signed and unsigned addition.
Usage	Carry Detection (unsigned operands):
	Following an add operation, a carry out of the MSB can be detected by checking whether the unsigned sum is less than one of the unsigned operands. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. The following code shows both cases:
	add rC, rA, rB
	cmpltu rD, rC, rA
	add rC, rA, rB
	bltu rC, rA, label
	# The original add operation
	# rD is written with the carry bit
	# The original add operation
	# Branch if carry generated
	Overflow Detection (signed operands):
	An overflow is detected when two positives are added and the sum is negative, or when two negatives are added and the sum is positive. The overflow condition can control a conditional branch, as shown in the following code:
	add rC, rA, rB
	xor rD, rC, rA
	xor rE, rC, rB
	and rD, rD, rE
	blt rD, r0,label
	# The original add operation
	# Compare signs of sum and rA
	# Compare signs of sum and rB
	# Combine comparisons
	# Branch if overflow occurred
Exceptions	None
Instruction Type	R

Instruction Fields

A = Register index of operand rA

B = Register index of operand rB

C = Register index of operand rC

addi

Instruction	addi
Operation	rB ← rA + σ(IMM16)
Assembler Syntax	`addi rB, rA, IMM16`
Example	`addi r6, r7, -100`
Description	Sign-extends the 16-bit immediate value and adds it to the value of rA. Stores the sum in rB.

Usage	Carry Detection (unsigned operands):
	Following an addi operation, a carry out of the MSB can be detected by checking whether the unsigned sum is less than one of the unsigned operands. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. The following code shows both cases:
	``addi rB, rA, IMM16``
	``cmpltu rD, rB, rA``
	``addi rB, rA, IMM16``
	``bltu rB, rA, label``
	``# The original add operation``
	``# rD is written with the carry bit``
	``# The original add operation``
	``# Branch if carry generated``
	Overflow Detection (signed operands):
	An overflow is detected when two positives are added and the sum is negative, or when two negatives are added and the sum is positive. The overflow condition can control a conditional branch, as shown in the following code:
	``addi rB, rA, IMM16``
	``xor rC, rB, rA``
	``xorhi rD, rB, IMM16``
	``and rC, rC, rD``
	``blt rC, r0,label``
	``# The original add operation``
	``# Compare signs of sum and rA``
	``# Compare signs of sum and IMM16``
	``# Combine comparisons``
	``# Branch if overflow occurred``
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit signed immediate value

IMM16										0x04					

and

Instruction	bitwise logical and
Operation	rC ← rA & rB
Assembler Syntax	`and rC, rA, rB`
Example	`and r6, r7, r8`
Description	Calculates the bitwise logical AND of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x0e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0e					0					0x3A					

andhi

Instruction	bitwise logical and immediate into high halfword
Operation	rB ← rA & (IMM16 : 0x0000)
Assembler Syntax	`andhi rB, rA, IMM16`

Example	`andhi r6, r7, 100`
Description	Calculates the bitwise logical AND of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x2c					

andi

Instruction	bitwise logical and immediate
Operation	rB ← rA & (0x0000 : IMM16)
Assembler Syntax	`andi rB, rA, IMM16`
Example	`andi r6, r7, 100`
Description	Calculates the bitwise logical AND of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Fields															
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x0c					

beq

Instruction	branch if equal
Operation	if (rA == rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`beq rA, rB, label`
Example	`beq r6, r7, label`
Description	If rA == rB, then `beq` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `beq`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x26					

bge

Instruction	branch if greater than or equal signed
Operation	if ((signed) rA >= (signed) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bge rA, rB, label`
Example	`bge r6, r7, top_of_loop`
Description	If (signed) rA >= (signed) rB, then `bge` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bge`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x0e					

bgeu

Instruction	branch if greater than or equal unsigned
Operation	if ((unsigned) rA >= (unsigned) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bgeu rA, rB, label`
Example	`bgeu r6, r7, top_of_loop`

Description	If (unsigned) rA >= (unsigned) rB, then `bgeu` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bgeu`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x2e					

bgt

Instruction	branch if greater than signed
Operation	if ((signed) rA > (signed) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bgt rA, rB, label`
Example	`bgt r6, r7, top_of_loop`
Description	If (signed) rA > (signed) rB, then `bgt` transfers program control to the instruction at label.
Pseudo-instruction	`bgt` is implemented with the `blt` instruction by swapping the register operands.

bgtu

Instruction	branch if greater than unsigned

Operation	if ((unsigned) rA > (unsigned) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bgtu rA, rB, label`
Example	`bgtu r6, r7, top_of_loop`
Description	If (unsigned) rA > (unsigned) rB, then `bgtu` transfers program control to the instruction at label.
Pseudo-instruction	`bgtu` is implemented with the `bltu` instruction by swapping the register operands.

ble

Instruction	branch if less than or equal signed
Operation	if ((signed) rA <= (signed) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`ble rA, rB, label`
Example	`ble r6, r7, top_of_loop`
Description	If (signed) rA <= (signed) rB, then `ble` transfers program control to the instruction at label.
Pseudo-instruction	`ble` is implemented with the `bge` instruction by swapping the register operands.

bleu

Instruction	branch if less than or equal to unsigned
Operation	if ((unsigned) rA <= (unsigned) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bleu rA, rB, label`
Example	`bleu r6, r7, top_of_loop`

Description	If (unsigned) rA <= (unsigned) rB, then bleu transfers program counter to the instruction at label.
Pseudo-instruction	bleu is implemented with the bgeu instruction by swapping the register operands.

blt

Instruction	branch if less than signed
Operation	if ((signed) rA < (signed) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	blt rA, rB, label
Example	blt r6, r7, top_of_loop
Description	If (signed) rA < (signed) rB, then blt transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following blt. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x16					

bltu

Instruction	branch if less than unsigned

Operation	if ((unsigned) rA < (unsigned) rB)
	then PC ← PC + 4 + σ(IMM16)
	else PC ← PC + 4
Assembler Syntax	`bltu rA, rB, label`
Example	`bltu r6, r7, top_of_loop`
Description	If (unsigned) rA < (unsigned) rB, then `bltu` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bltu`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA
	`B` = Register index of operand rB
	`IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x36					

bne

Instruction	branch if not equal
Operation	if (rA != rB)
	then PC ← PC + 4 + σ(IMM16)
	else PC ← PC + 4
Assembler Syntax	`bne rA, rB, label`
Example	`bne r6, r7, top_of_loop`

Description	If rA != rB, then `bne` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bne`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x1e					

br

Instruction	unconditional branch
Operation	PC ← PC + 4 + σ(IMM16)
Assembler Syntax	`br label`
Example	`br top_of_loop`
Description	Transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `br`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						0				IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x06					

break

Instruction	debugging breakpoint
Operation	bstatus ← status PIE ← 0 U ← 0 ba ← PC + 4 PC ← break handler address

Assembler Syntax	`break`
	
	`break imm5`

Example	`break`
Description	Breaks program execution and transfers control to the debugger break-processing routine. Saves the address of the next instruction in register `ba` and saves the contents of the `status` register in `bstatus`. Disables interrupts, then transfers execution to the break handler. The 5-bit immediate field `imm5` is ignored by the processor, but it can be used by the debugger. `break` with no argument is the same as `break 0`.
Usage	`break` is used by debuggers exclusively. Only debuggers should place `break` in a user program, operating system, or exception handler. The address of the break handler is specified with the Nios_II Processor parameter editor in Qsys. Some debuggers support `break` and `break 0` instructions in source code. These debuggers treat the `break` instruction as a normal breakpoint.
Exceptions	Break
Instruction Type	R
Instruction Fields	`IMM5` = Type of breakpoint

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0x1e					0x34
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x34					IMM5					0x3a					

bret

Instruction	breakpoint return
Operation	status ← bstatus PC ← ba
Assembler Syntax	bret
Example	bret
Description	Copies the value of bstatus to the status register, then transfers execution to the address in ba.
Usage	bret is used by debuggers exclusively and should not appear in user programs, operating systems, or exception handlers.
Exceptions	Misaligned destination address Supervisor-only instruction
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1e					0					0x1e					0x09
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x09					0					0x3a					

call

Instruction	call subroutine

Operation	$ra \leftarrow PC + 4$ $PC \leftarrow (PC_{31..28} : IMM26 \times 4)$
Assembler Syntax	`call label`
Example	`call write_char`
Description	Saves the address of the next instruction in register `ra`, and transfers execution to the instruction at address ($PC_{31..28}$: IMM26 x 4).
Usage	`call` can transfer execution anywhere within the 256-MB range determined by $PC_{31..28}$. The Nios II GNU linker does not automatically handle cases in which the address is out of this range.
Exceptions	None
Instruction Type	J
Instruction Fields	`IMM26` = 26-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IMM26															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM26										0					

callr

Instruction	call subroutine in register
Operation	$ra \leftarrow PC + 4$ $PC \leftarrow rA$
Assembler Syntax	`callr rA`
Example	`callr r6`
Description	Saves the address of the next instruction in the return address register, and transfers execution to the address contained in register rA.
Usage	`callr` is used to dereference C-language function pointers.

Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	A = Register index of operand rA

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					0x1f					0x1d
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1d					0					0x3a					

cmpeq

Instruction	compare equal
Operation	if (rA == rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpeq rC, rA, rB`
Example	`cmpeq r6, r7, r8`
Description	If rA == rB, then stores 1 to rC; otherwise, stores 0 to rC.

Usage	`cmpeq` performs the == operation of the C programming language. Also, `cmpeq` can be used to implement the C logical negation operator "!".
	
	`cmpeq rC, rA, r0`
	
	`# Implements rC = !rA`

Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x20
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x20					0					0x3a					

cmpeqi

Instruction	compare equal immediate
Operation	if (rA σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpeqi rB, rA, IMM16`
Example	`cmpeqi r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA == σ(IMM16), `cmpeqi` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpeqi` performs the == operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x20					

cmpge

Instruction	compare greater than or equal signed
Operation	if ((signed) rA >= (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	cmpge rC, rA, rB
Example	cmpge r6, r7, r8
Description	If rA >= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	cmpge performs the signed >= operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A						B					C			0x08
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0x08						0					0x3a			

cmpgei

Instruction	compare greater than or equal signed immediate
Operation	if ((signed) rA >= (signed) σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	cmpgei rB, rA, IMM16
Example	cmpgei r6, r7, 100

Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA >= σ(IMM16), then `cmpgei` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgei` performs the signed >= operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA
	`B` = Register index of operand rB
	`IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A					B						IMM16			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
			IMM16									0x08			

cmpgeu

Instruction	compare greater than or equal unsigned
Operation	if ((unsigned) rA >= (unsigned) rB)
	then rC ← 1
	else rC ← 0
Assembler Syntax	`cmpgeu rC, rA, rB`
Example	`cmpgeu r6, r7, r8`
Description	If rA >= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpgeu` performs the unsigned >= operation of the C programming language.
Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x28
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x28					0					0x3a					

cmpgeui

Instruction	compare greater than or equal unsigned immediate
Operation	if ((unsigned) rA >= (unsigned) (0x0000 : IMM16))
	then rB ← 1
	else rB ← 0
Assembler Syntax	`cmpgeui rB, rA, IMM16`
Example	`cmpgeui r6, r7, 100`
Description	Zero-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA >= (0x0000 : IMM16), then `cmpgeui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgeui` performs the unsigned >= operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					

Bit Fields															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x28					

cmpgt

Instruction	compare greater than signed
Operation	if ((signed) rA > (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpgt rC, rA, rB`
Example	`cmpgt r6, r7, r8`
Description	If rA > rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpgt` performs the signed > operation of the C programming language.
Pseudo-instruction	`cmpgt` is implemented with the `cmplt` instruction by swapping its rA and rB operands.

cmpgti

Instruction	compare greater than signed immediate
Operation	if ((signed) rA > (signed) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpgti rB, rA, IMMED`
Example	`cmpgti r6, r7, 100`
Description	Sign-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA > σ(IMMED), then `cmpgti` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgti` performs the signed > operation of the C programming language. The maximum allowed value of IMMED is 32766. The minimum allowed value is −32769.

Pseudo-instruction	cmpgti is implemented using a cmpgei instruction with an IMM16 immediate value of IMMED + 1.

cmpgtu

Instruction	compare greater than unsigned
Operation	if ((unsigned) rA > (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	cmpgtu rC, rA, rB
Example	cmpgtu r6, r7, r8
Description	If rA > rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	cmpgtu performs the unsigned > operation of the C programming language.
Pseudo-instruction	cmpgtu is implemented with the cmpltu instruction by swapping its rA and rB operands.

cmpgtui

Instruction	compare greater than unsigned immediate
Operation	if ((unsigned) rA > (unsigned) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	cmpgtui rB, rA, IMMED
Example	cmpgtui r6, r7, 100
Description	Zero-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA > IMMED, then cmpgtui stores 1 to rB; otherwise stores 0 to rB.
Usage	cmpgtui performs the unsigned > operation of the C programming language. The maximum allowed value of IMMED is 65534. The minimum allowed value is 0.

Pseudo-instruction	cmpgtui is implemented using a cmpgeui instruction with an IMM16 immediate value of IMMED + 1.

cmple

Instruction	compare less than or equal signed
Operation	if ((signed) rA <= (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	cmple rC, rA, rB
Example	cmple r6, r7, r8
Description	If rA <= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	cmple performs the signed <= operation of the C programming language.
Pseudo-instruction	cmple is implemented with the cmpge instruction by swapping its rA and rB operands.

cmplei

Instruction	compare less than or equal signed immediate
Operation	if ((signed) rA < (signed) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	cmplei rB, rA, IMMED
Example	cmplei r6, r7, 100
Description	Sign-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA <= σ(IMMED), then cmplei stores 1 to rB; otherwise stores 0 to rB.
Usage	cmplei performs the signed <= operation of the C programming language. The maximum allowed value of IMMED is 32766. The minimum allowed value is –32769.

Pseudo-instruction	`cmplei` is implemented using a `cmplti` instruction with an IMM16 immediate value of IMMED + 1.

cmpleu

Instruction	compare less than or equal unsigned
Operation	if ((unsigned) rA < (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpleu rC, rA, rB`
Example	`cmpleu r6, r7, r8`
Description	If rA <= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpleu` performs the unsigned <= operation of the C programming language.
Pseudo-instruction	`cmpleu` is implemented with the `cmpgeu` instruction by swapping its rA and rB operands.

cmpleui

Instruction	compare less than or equal unsigned immediate
Operation	if ((unsigned) rA <= (unsigned) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpleui rB, rA, IMMED`
Example	`cmpleui r6, r7, 100`
Description	Zero-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA <= IMMED, then `cmpleui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpleui` performs the unsigned <= operation of the C programming language. The maximum allowed value of IMMED is 65534. The minimum allowed value is 0.

Pseudo-instruction	cmpleui is implemented using a cmpltui instruction with an IMM16 immediate value of IMMED + 1.

cmplt

Instruction	compare less than signed
Operation	if ((signed) rA < (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	cmplt rC, rA, rB
Example	cmplt r6, r7, r8
Description	If rA < rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	cmplt performs the signed < operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x10
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x10					0					0x3a					

cmplti

Instruction	compare less than signed immediate

Operation	if ((signed) rA < (signed) σ(IMM16))
	then rB ← 1
	else rB ← 0
Assembler Syntax	`cmplti rB, rA, IMM16`
Example	`cmplti r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA < σ(IMM16), then `cmplti` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmplti` performs the signed < operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA
	`B` = Register index of operand rB
	`IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A						B					IMM16			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IMM16										0x10				

cmpltu

Instruction	compare less than unsigned
Operation	if ((unsigned) rA < (unsigned) rB)
	then rC ← 1
	else rC ← 0
Assembler Syntax	`cmpltu rC, rA, rB`
Example	`cmpltu r6, r7, r8`
Description	If rA < rB, then stores 1 to rC; otherwise stores 0 to rC.

Usage	`cmpltu` performs the unsigned < operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA
	`B` = Register index of operand rB
	`C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x30
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x30					0					0x3a					

cmpltui

Instruction	compare less than unsigned immediate
Operation	if ((unsigned) rA < (unsigned) (0x0000 : IMM16))
	then rB ← 1
	else rB ← 0
Assembler Syntax	`cmpltui rB, rA, IMM16`
Example	`cmpltui r6, r7, 100`
Description	Zero-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA < (0x0000 : IMM16), then `cmpltui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpltui` performs the unsigned < operation of the C programming language.
Exceptions	None
Instruction Type	I

Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x30					

cmpne

Instruction	compare not equal
Operation	if (rA != rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpne rC, rA, rB`
Example	`cmpne r6, r7, r8`
Description	If rA != rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpne` performs the != operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x18
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Fields		
0x18	0	0x3a

cmpnei

Instruction	compare not equal immediate
Operation	if (rA != σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpnei rB, rA, IMM16`
Example	`cmpnei r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA != σ(IMM16), then `cmpnei` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpnei` performs the != operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x18					

custom

Instruction	custom instruction

Operation	if c == 1
	then rC ← f_N(rA, rB, A, B, C)
	else Ø ← f_N(rA, rB, A, B, C)
Assembler Syntax	`custom N, xC, xA, xB`
	Where xA means either general purpose register rA, or custom register cA.
Example	`custom 0, c6, r7, r8`
Description	The `custom` opcode provides access to up to 256 custom instructions allowed by the Nios II architecture. The function implemented by a custom instruction is user-defined and is specified with the Nios_II Processor parameter editor in Qsys. The 8-bit immediate N field specifies which custom instruction to use. Custom instructions can use up to two parameters, xA and xB, and can optionally write the result to a register xC.
Usage	To access a custom register inside the custom instruction logic, clear the bit readra, readrb, or writerc that corresponds to the register field. In assembler syntax, the notation cN refers to register N in the custom register file and causes the assembler to clear the c bit of the opcode. For example, `custom 0, c3, r5, r0` performs custom instruction 0, operating on general-purpose registers r5 and r0, and stores the result in custom register 3.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand A
	B = Register index of operand B
	C = Register index of operand C
	readra = 1 if instruction uses rA, 0 otherwise
	readrb = 1 if instruction uses rB, 0 otherwise
	writerc = 1 if instruction provides result for rC, 0 otherwise
	N = 8-bit number that selects instruction

div

Instruction	divide
Operation	rC ← rA ÷ rB
Assembler Syntax	`div rC, rA, rB`
Example	`div r6, r7, r8`
Description	Treating rA and rB as signed integers, this instruction divides rA by rB and then stores the integer portion of the resulting quotient to rC. After attempted division by zero, the value of rC is undefined. There is no divide-by-zero exception. After dividing –2147483648 by –1, the value of rC is undefined (the number +2147483648 is not representable in 32 bits). There is no overflow exception.

Nios II processors that do not implement the `div` instruction cause an unimplemented instruction exception. |
| Usage | Remainder of Division:

If the result of the division is defined, then the remainder can be computed in rD using the following instruction sequence:

`div rC, rA, rB`

`mul rD, rC, rB`

`sub rD, rA, rD`

`# The original div operation`

`# rD = remainder` |
| Exceptions | Division error

Unimplemented instruction |
| Instruction Type | R |
| Instruction Fields | A = Register index of operand rA

B = Register index of operand rB

C = Register index of operand rC |

divu

Instruction	divide unsigned
Operation	rC ← rA ÷ rB
Assembler Syntax	`divu rC, rA, rB`
Example	`divu r6, r7, r8`
Description	Treating rA and rB as unsigned integers, this instruction divides rA by rB and then stores the integer portion of the resulting quotient to rC. After attempted division by zero, the value of rC is undefined. There is no divide-by-zero exception. Nios II processors that do not implement the `divu` instruction cause an unimplemented instruction exception.

Usage	Remainder of Division:
	
	If the result of the division is defined, then the remainder can be computed in rD using the following instruction sequence:
	
	`divu rC, rA, rB`
	`mul rD, rC, rB`
	`sub rD, rA, rD`
	`# The original divu operation`
	`# rD = remainder`

Exceptions	Division error Unimplemented instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields

eret

Instruction	exception return
Operation	status ← estatus PC ← ea
Assembler Syntax	eret
Example	eret
Description	Copies the value of estatus into the status register, and transfers execution to the address in ea.
Usage	Use eret to return from traps, external interrupts, and other exception handling routines. Note that before returning from hardware interrupt exceptions, the exception handler must adjust the ea register.
Exceptions	Misaligned destination address Supervisor-only instruction
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1d					0x1e					C					0x01

0x01					0					0x3a					

flushd

Instruction	flush data cache line

Operation	Flushes the data cache line associated with address rA + σ(IMM16).
Assembler Syntax	`flushd IMM16(rA)`
Example	`flushd -100(r6)`
Description	If the Nios II processor implements a direct mapped data cache, `flushd` writes the data cache line that is mapped to the specified address back to memory if the line is dirty, and then clears the data cache line. Unlike `flushda`, `flushd` writes the dirty data back to memory even when the addressed data is not currently in the cache. This process comprises the following steps:
	• Compute the effective address specified by the sum of rA and the signed 16-bit immediate value.
	• Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the data cache line, `flushd` ignores the `tag` field and only uses the `line` field to select the data cache line to clear.
	• Skip comparing the cache line tag with the effective address to determine if the addressed data is currently cached. Because `flushd` ignores the cache line tag, `flushd` flushes the cache line regardless of whether the specified data location is currently cached.
	• If the data cache line is dirty, write the line back to memory. A cache line is dirty when one or more words of the cache line have been modified by the processor, but are not yet written to memory.
	• Clear the valid bit for the line.
	If the Nios II processor core does not have a data cache, the `flushd` instruction performs no operation.
Usage	Use `flushd` to write dirty lines back to memory even if the addressed memory location is not in the cache, and then flush the cache line. By contrast, refer to "flushda flush data cache address", "initd initialize data cache line", and "initda initialize data cache address" for other cache-clearing options.
	For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA
	`IMM16` = 16-bit signed immediate value

Bit Fields

flushda

Instruction	flush data cache address
Operation	Flushes the data cache line currently caching address $rA + \sigma(IMM16)$
Assembler Syntax	`flushda IMM16(rA)`
Example	`flushda -100(r6)`

Description	If the Nios II processor implements a direct mapped data cache, `flushda` writes the data cache line that is mapped to the specified address back to memory if the line is dirty, and then clears the data cache line. Unlike `flushd`, `flushda` writes the dirty data back to memory only when the addressed data is currently in the cache. This process comprises the following steps:
	• Compute the effective address specified by the sum of rA and the signed 16-bit immediate value.
	• Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `flushda` uses both the `tag` field and the `line` field.
	• Compare the cache line tag with the effective address to determine if the addressed data is currently cached. If the `tag` fields do not match, the effective address is not currently cached, so the instruction does nothing.
	• If the data cache line is dirty and the `tag` fields match, write the dirty cache line back to memory. A cache line is dirty when one or more words of the cache line have been modified by the processor, but are not yet written to memory.
	• Clear the valid bit for the line.
	If the Nios II processor core does not have a data cache, the `flushda` instruction performs no operation.
Usage	Use `flushda` to write dirty lines back to memory only if the addressed memory location is currently in the cache, and then flush the cache line. By contrast, refer to "flushd flush data cache line", "initd initialize data cache line", and "initda initialize data cache address" for other cache-clearing options.
	For more information on the Nios II data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address
	Fast TLB miss (data)
	Double TLB miss (data)
	MPU region violation (data)

flushi

Instruction	flush instruction cache line
Operation	Flushes the instruction cache line associated with address rA.
Assembler Syntax	`flushi rA`
Example	`flushi r6`
Description	Ignoring the tag, `flushi` identifies the instruction cache line associated with the byte address in rA, and invalidates that line.
	If the Nios II processor core does not have an instruction cache, the `flushi` instruction performs no operation.
	For more information about the data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA

Cache and Tightly-Coupled Memory

flushp

Instruction	flush pipeline
Operation	Flushes the processor pipeline of any prefetched instructions.
Assembler Syntax	`flushp`
Example	`flushp`
Description	Ensures that any instructions prefetched after the `flushp` instruction are removed from the pipeline.
Usage	Use `flushp` before transferring control to newly updated instruction memory.
Exceptions	None
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x04					0					0x3a					

initd

Instruction	initialize data cache line
Operation	Initializes the data cache line associated with address rA + σ(IMM16).
Assembler Syntax	`initd IMM16(rA)`
Example	`initd 0(r6)`

Description	If the Nios II processor implements a direct mapped data cache, `initd` clears the data cache line without checking for (or writing) a dirty data cache line that is mapped to the specified address back to memory. Unlike `initda`, `initd` clears the cache line regardless of whether the addressed data is currently cached. This process comprises the following steps:

- Compute the effective address specified by the sum of rA and the signed 16-bit immediate value.
- Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `initd` ignores the `tag` field and only uses the `line` field to select the data cache line to clear.
- Skip comparing the cache line tag with the effective address to determine if the addressed data is currently cached. Because `initd` ignores the cache line tag, `initd` flushes the cache line regardless of whether the specified data location is currently cached.
- Skip checking if the data cache line is dirty. Because `initd` skips the dirty cache line check, data that has been modified by the processor, but not yet written to memory is lost.
- Clear the valid bit for the line.

If the Nios II processor core does not have a data cache, the `initd` instruction performs no operation.

| Usage | Use `initd` after processor reset and before accessing data memory to initialize the processor's data cache. Use `initd` with caution because it does not write back dirty data. By contrast, refer to "flushd flush data cache line", "flushda flush data cache address", and "initda initialize data cache address" for other cache-clearing options. Altera recommends using `initd` only when the processor comes out of reset.

For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*. |

initda

Instruction	initialize data cache address
Operation	Initializes the data cache line currently caching address rA + σ(IMM16)
Assembler Syntax	`initda IMM16(rA)`
Example	`initda -100(r6)`
Description	If the Nios II processor implements a direct mapped data cache, `initda` clears the data cache line without checking for (or writing) a dirty data cache line that is mapped to the specified address back to memory. Unlike `initd`, `initda` clears the cache line only when the addressed data is currently cached. This process comprises the following steps: • Compute the effective address specified by the sum of rA and the signed 16-bit immediate value. • Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `initda` uses both the `tag` field and the `line` field. • Compare the cache line tag with the effective address to determine if the addressed data is currently cached. If the `tag` fields do not match, the effective address is not currently cached, so the instruction does nothing. • Skip checking if the data cache line is dirty. Because `initd` skips the dirty cache line check, data that has been modified by the processor, but not yet written to memory is lost. • Clear the valid bit for the line. If the Nios II processor core does not have a data cache, the `initda` instruction performs no operation.

Usage	Use `initda` to skip writing dirty lines back to memory and to flush the cache line only if the addressed memory location is currently in the cache. By contrast, refer to "flushd flush data cache line", "flushda flush data cache address", and "initd initialize data cache line" on page 8–55 for other cache-clearing options. Use `initda` with caution because it does not write back dirty data.
	For more information on the Nios II data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

initi

Instruction	initialize instruction cache line
Operation	Initializes the instruction cache line associated with address rA.
Assembler Syntax	`initi rA`

Example	`initi r6`
Description	Ignoring the tag, `initi` identifies the instruction cache line associated with the byte address in `ra`, and `initi` invalidates that line. If the Nios II processor core does not have an instruction cache, the `initi` instruction performs no operation.
Usage	This instruction is used to initialize the processor's instruction cache. Immediately after processor reset, use `initi` to invalidate each line of the instruction cache. For more information on instruction cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Cache and Tightly-Coupled Memory

jmp

Instruction	computed jump
Operation	PC ← rA
Assembler Syntax	`jmp rA`
Example	`jmp r12`
Description	Transfers execution to the address contained in register rA.

Usage	It is illegal to jump to the address contained in register r31. To return from subroutines called by `call` or `callr`, use `ret` instead of `jmp`.
Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x0d					0					0x3a					

jmpi

Instruction	jump immediate
Operation	PC $\leftarrow$ (PC$_{31..28}$: IMM26 x 4)
Assembler Syntax	`jmpi label`
Example	`jmpi write_char`
Description	Transfers execution to the instruction at address (PC$_{31..28}$: IMM26 x 4).
Usage	`jmpi` is a low-overhead local jump. `jmpi` can transfer execution anywhere within the 256-MB range determined by PC$_{31..28}$. The Nios II GNU linker does not automatically handle cases in which the address is out of this range.
Exceptions	None
Instruction Type	J
Instruction Fields	`IMM26` = 26-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ldb / ldbio

Instruction	load byte from memory or I/O peripheral
Operation	rB ← σ(Mem8[rA + σ(IMM16)])
Assembler Syntax	`ldb rB, byte_offset(rA)` `ldbio rB, byte_offset(rA)`
Example	`ldb r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the desired memory byte, sign extending the 8-bit value to 32 bits. In Nios II processor cores with a data cache, this instruction may retrieve the desired data from the cache instead of from memory.
Usage	Use the `ldbio` instruction for peripheral I/O. In processors with a data cache, `ldbio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `ldbio` acts like `ldb`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (read) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)

Cache and Tightly-Coupled Memory

ldbu / ldbuio

Instruction	load unsigned byte from memory or I/O peripheral
Operation	rB ← 0x000000 : Mem8[rA + σ(IMM16)]
Assembler Syntax	ldbu rB, byte_offset(rA) ldbuio rB, byte_offset(rA)
Example	ldbu r6, 100(r5)
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the desired memory byte, zero extending the 8-bit value to 32 bits.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the ldbuio instruction for peripheral I/O. In processors with a data cache, ldbuio bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, ldbuio acts like ldbu. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Exceptions	Supervisor-only data address
	Misaligned data address

Cache and Tightly-Coupled Memory

ldh / ldhio

Instruction	load halfword from memory or I/O peripheral
Operation	rB ← σ(Mem16[rA + σ(IMM16)])
Assembler Syntax	`ldh rB, byte_offset(rA)`
	`ldhio rB, byte_offset(rA)`

Example	`ldh r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory halfword located at the effective byte address, sign extending the 16-bit value to 32 bits. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldhio` instruction for peripheral I/O. In processors with a data cache, `ldhio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `ldhio` acts like `ldh`.
	For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Cache and Tightly-Coupled Memory

ldhu / ldhuio

Instruction	load unsigned halfword from memory or I/O peripheral
Operation	$rB \leftarrow 0x0000 : Mem16[rA + \sigma(IMM16)]$
Assembler Syntax	`ldhu rB, byte_offset(rA)` `ldhuio rB, byte_offset(rA)`
Example	`ldhu r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory halfword located at the effective byte address, zero extending the 16-bit value to 32 bits. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldhuio` instruction for peripheral I/O. In processors with a data cache, `ldhuio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `ldhuio` acts like `ldhu`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Exceptions	Supervisor-only data address
	Misaligned data address
	TLB permission violation (read)
	Fast TLB miss (data)
	Double TLB miss (data)
	MPU region violation (data)
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit signed immediate value

Related Information
Cache and Tightly-Coupled Memory

ldw / ldwio

Instruction	load 32-bit word from memory or I/O peripheral
Operation	rB ← Mem32[rA + σ(IMM14)]
Assembler Syntax	ldw rB, byte_offset(rA)
	ldwio rB, byte_offset(rA)

Example	`ldw r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory word located at the effective byte address. The effective byte address must be word aligned. If the byte address is not a multiple of 4, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldwio` instruction for peripheral I/O. In processors with a data cache, `ldwio` bypasses the cache and memory. Use the `ldwio` instruction for peripheral I/O. In processors with a data cache, `ldwio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `ldwio` acts like `ldw`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Related Information

Cache and Tightly-Coupled Memory

mov

Instruction	move register to register
Operation	rC ← rA
Assembler Syntax	`mov rC, rA`
Example	`mov r6, r7`
Description	Moves the contents of rA to rC.
Pseudo-instruction	`mov` is implemented as `add rC, rA, r0`.

movhi

Instruction	move immediate into high halfword
Operation	rB ← (IMMED : 0x0000)
Assembler Syntax	`movhi rB, IMMED`
Example	`movhi r6, 0x8000`
Description	Writes the immediate value IMMED into the high halfword of rB, and clears the lower halfword of rB to 0x0000.

Usage	The maximum allowed value of IMMED is 65535. The minimum allowed value is 0. To load a 32-bit constant into a register, first load the upper 16 bits using a `movhi` pseudo-instruction. The `%hi()` macro can be used to extract the upper 16 bits of a constant or a label. Then, load the lower 16 bits with an `ori` instruction. The `%lo()` macro can be used to extract the lower 16 bits of a constant or label as shown in the following code:

	`movhi rB, %hi(value)`
	
	`ori rB, rB, %lo(value)`
	
	An alternative method to load a 32-bit constant into a register uses the %hiadj() macro and the `addi` instruction as shown in the following code:
	
	`movhi rB, %hiadj(value)`
	
	`addi rB, rB, %lo(value)`

Pseudo-instruction	`movhi` is implemented as `orhi rB, r0, IMMED`.

movi

Instruction	move signed immediate into word
Operation	rB ← σ(IMMED)
Assembler Syntax	`movi rB, IMMED`
Example	`movi r6, -30`
Description	Sign-extends the immediate value IMMED to 32 bits and writes it to rB.
Usage	The maximum allowed value of IMMED is 32767. The minimum allowed value is –32768. To load a 32-bit constant into a register, refer to the `movhi` instruction.
Pseudo-instruction	`movi` is implemented as `addi rB, r0, IMMED`.

movia

Instruction	move immediate address into word
Operation	rB ← label

Assembler Syntax	`movia rB, label`
Example	`movia r6, function_address`
Description	Writes the address of label to rB.

Pseudo-instruction	`movia` is implemented as:
	
	`orhi rB, r0, %hiadj(label)`
	
	`addi rB, rB, %lo(label)`

movui

Instruction	move unsigned immediate into word
Operation	rB ← (0x0000 : IMMED)
Assembler Syntax	`movui rB, IMMED`
Example	`movui r6, 100`
Description	Zero-extends the immediate value IMMED to 32 bits and writes it to rB.
Usage	The maximum allowed value of IMMED is 65535. The minimum allowed value is 0. To load a 32-bit constant into a register, refer to the `movhi` instruction.
Pseudo-instruction	`movui` is implemented as `ori rB, r0, IMMED`.

mul

Instruction	multiply
Operation	rC ← (rA x rB) $_{31..0}$
Assembler Syntax	`mul rC, rA, rB`
Example	`mul r6, r7, r8`
Description	Multiplies rA times rB and stores the 32 low-order bits of the product to rC. The result is the same whether the operands are treated as signed or unsigned integers. Nios II processors that do not implement the `mul` instruction cause an unimplemented instruction exception.

Usage	Carry Detection (unsigned operands):
	Before or after the multiply operation, the carry out of the MSB of rC can be detected using the following instruction sequence:
| | ```
mul rC, rA, rB

mulxuu rD, rA, rB

cmpne rD, rD, r0

# The mul operation (optional)

# rD is nonzero if carry occurred

# rD is 1 if carry occurred, 0 if not
``` |
	The `mulxuu` instruction writes a nonzero value into rD if the multiplication of unsigned numbers generates a carry (unsigned overflow). If a 0/1 result is desired, follow the `mulxuu` with the `cmpne` instruction.
	Overflow Detection (signed operands):
	After the multiply operation, overflow can be detected using the following instruction sequence:
| | ```
mul rC, rA, rB

cmplt rD, rC, r0

mulxss rE, rA, rB

add rD, rD, rE

cmpne rD, rD, r0

# The original mul operation

# rD is nonzero if overflow

# rD is 1 if overflow, 0 if not
``` |
	The `cmplt-mulxss-add` instruction sequence writes a nonzero value into rD if the product in rC cannot be represented in 32 bits (signed overflow). If a 0/1 result is desired, follow the instruction sequence with the `cmpne` instruction.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields

0x27					0					0x3a					

muli

Instruction	multiply immediate
Operation	$rB \leftarrow (rA \times \sigma(IMM16))_{31..0}$
Assembler Syntax	`muli rB, rA, IMM16`
Example	`muli r6, r7, -100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and multiplies it by the value of rA. Stores the 32 low-order bits of the product to rB. The result is independent of whether rA is treated as a signed or unsigned number. Nios II processors that do not implement the `muli` instruction cause an unimplemented instruction exception. Carry Detection and Overflow Detection: For a discussion of carry and overflow detection, refer to the `mul` instruction.
Exceptions	Unimplemented instruction
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

mulxss

Instruction	multiply extended signed/signed
Operation	rC ← ((signed) rA) x ((signed) rB)) $_{63..32}$
Assembler Syntax	`mulxss rC, rA, rB`
Example	`mulxss r6, r7, r8`
Description	Treating rA and rB as signed integers, `mulxss` multiplies rA times rB, and stores the 32 high-order bits of the product to rC. Nios II processors that do not implement the `mulxss` instruction cause an unimplemented instruction exception.
Usage	Use `mulxss` and `mul` to compute the full 64-bit product of two 32-bit signed integers. Furthermore, `mulxss` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxss` and `mul` instructions are used to calculate the 64-bit product S1 x S2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

mulxsu

Instruction	multiply extended signed/unsigned
Operation	rC ← ((signed) rA) x ((unsigned) rB)) $_{63..32}$

Assembler Syntax	`mulxsu rC, rA, rB`
Example	`mulxsu r6, r7, r8`
Description	Treating rA as a signed integer and rB as an unsigned integer, `mulxsu` multiplies rA times rB, and stores the 32 high-order bits of the product to rC. Nios II processors that do not implement the `mulxsu` instruction cause an unimplemented instruction exception.
Usage	`mulxsu` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is: (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxsu` and `mul` instructions are used to calculate the two 64-bit products S1 x U2 and U1 x S2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields

mulxuu

Instruction	multiply extended unsigned/unsigned
Operation	rC ← ((unsigned) rA) x ((unsigned) rB)) $_{63..32}$
Assembler Syntax	`mulxuu rC, rA, rB`
Example	`mulxuu r6, r7, r8`

Description	Treating rA and rB as unsigned integers, `mulxuu` multiplies rA times rB and stores the 32 high-order bits of the product to rC.
	Nios II processors that do not implement the `mulxuu` instruction cause an unimplemented instruction exception.
Usage	Use `mulxuu` and `mul` to compute the 64-bit product of two 32-bit unsigned integers. Furthermore, `mulxuu` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit signed integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxuu` and `mul` instructions are used to calculate the 64-bit product U1 x U2.
	`mulxuu` also can be used as part of the calculation of a 128-bit product of two 64-bit unsigned integers. Given two 64-bit unsigned integers, each contained in a pair of 32-bit registers, (T1 : U1) and (T2 : U2), their 128-bit product is (U1 x U2) + ((U1 x T2) << 32) + ((T1 x U2) << 32) + ((T1 x T2) << 64). The `mulxuu` and `mul` instructions are used to calculate the four 64-bit products U1 x U2, U1 x T2, T1 x U2, and T1 x T2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

nextpc

Instruction	get address of following instruction
Operation	rC ← PC + 4
Assembler Syntax	`nextpc rC`
Example	`nextpc r6`

Description	Stores the address of the next instruction to register rC.
Usage	A relocatable code fragment can use `nextpc` to calculate the address of its data segment. `nextpc` is the only way to access the PC directly.
Exceptions	None
Instruction Type	R
Instruction Fields	`C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		0x1c					0					0x3a			

nop

Instruction	no operation
Operation	None
Assembler Syntax	`nop`
Example	`nop`
Description	`nop` does nothing.
Pseudo-instruction	`nop` is implemented as `add r0, r0, r0`.

nor

Instruction	bitwise logical nor
Operation	rC ← ~(rA | rB)
Assembler Syntax	`nor rC, rA, rB`
Example	`nor r6, r7, r8`

Description	Calculates the bitwise logical NOR of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A					B					C					0x06						0					0x3a					

or

Instruction	bitwise logical or
Operation	rC ← rA | rB
Assembler Syntax	or rC, rA, rB
Example	or r6, r7, r8
Description	Calculates the bitwise logical OR of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0x16					0					0x3a				

orhi

Instruction	bitwise logical or immediate into high halfword
Operation	rB ← rA | (IMM16 : 0x0000)
Assembler Syntax	`orhi rB, rA, IMM16`
Example	`orhi r6, r7, 100`
Description	Calculates the bitwise logical OR of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IMM16										0x34					

ori

Instruction	bitwise logical or immediate
Operation	rB ← rA | (0x0000 : IMM16)
Assembler Syntax	`ori rB, rA, IMM16`
Example	`ori r6, r7, 100`
Description	Calculates the bitwise logical OR of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I

Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rdctl

Instruction	read from control register
Operation	rC ← ctlN
Assembler Syntax	rdctl rC, ctlN
Example	rdctl r3, ctl31
Description	Reads the value contained in control register ctlN and writes it to register rC.
Exceptions	Supervisor-only instruction
Instruction Type	R
Instruction Fields	C = Register index of operand rC
	N = Control register index of operand ctlN

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					C					0x26
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x26					N					0x3a					

rdprs

Instruction	read from previous register set

Operation	rB ← prs.rA + σ(IMM16)
Assembler Syntax	`rdprs rB, rA, IMM16`
Example	`rdprs r6, r7, 0`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits, and adds it to the value of rA from the previous register set. Places the result in rB in the current register set.
Usage	The previous register set is specified by status.PRS. By default, status.PRS indicates the register set in use before an exception, such as an external interrupt, caused a register set change. To read from an arbitrary register set, software can insert the desired register set number in `status.PRS` prior to executing `rdprs`. If shadow register sets are not implemented on the Nios II core, `rdprs` is an illegal instruction.
Exceptions	Supervisor-only instruction Illegal instruction
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x38					

ret

Instruction	return from subroutine
Operation	PC ← `ra`
Assembler Syntax	`ret`
Example	`ret`

Description	Transfers execution to the address in ra.
Usage	Any subroutine called by call or callr must use ret to return.
Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1f					0					0					0x05
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x05					0					0x3a					

rol

Instruction	rotate left
Operation	rC ← rA rotated left $rB_{4..0}$ bit positions
Assembler Syntax	rol rC, rA, rB
Example	rol r6, r7, r8
Description	Rotates rA left by the number of bits specified in $rB_{4..0}$ and stores the result in rC. The bits that shift out of the register rotate into the least-significant bit positions. Bits 31–5 of rB are ignored.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x03

Bit Fields															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x03					0					0x3a					

roli

Instruction	rotate left immediate
Operation	rC ← rA rotated left IMM5 bit positions
Assembler Syntax	`roli rC, rA, IMM5`
Example	`roli r6, r7, 3`
Description	Rotates rA left by the number of bits specified in IMM5 and stores the result in rC. The bits that shift out of the register rotate into the least-significant bit positions.
Usage	In addition to the rotate-left operation, roli can be used to implement a rotate-right operation. Rotating left by (32 – IMM5) bits is the equivalent of rotating right by IMM5 bits.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	C = Register index of operand rC
	IMM5 = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		A					0					C			0x02
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x02					IMM5					0x3a					

ror

Instruction	rotate right
Operation	rC ← rA rotated right $rB_{4..0}$ bit positions

Assembler Syntax	`ror rC, rA, rB`
Example	`ror r6, r7, r8`
Description	Rotates rA right by the number of bits specified in $rB_{4..0}$ and stores the result in rC. The bits that shift out of the register rotate into the most-significant bit positions. Bits 31– 5 of rB are ignored.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

sll

Instruction	shift left logical
Operation	$rC \leftarrow rA << (rB_{4..0})$
Assembler Syntax	`sll rC, rA, rB`
Example	`sll r6, r7, r8`
Description	Shifts rA left by the number of bits specified in $rB_{4..0}$ (inserting zeroes), and then stores the result in rC. `sll` performs the << operation of the C programming language.
Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x13
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x13					0					0x3a					

slli

Instruction	shift left logical immediate
Operation	rC ← rA << IMM5
Assembler Syntax	`slli rC, rA, IMM5`
Example	`slli r6, r7, 3`
Description	Shifts rA left by the number of bits specified in IMM5 (inserting zeroes), and then stores the result in rC.
Usage	`slli` performs the << operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	C = Register index of operand rC
	IMM5 = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x12
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x12					IMM5					0x3a					

sra

Instruction	shift right arithmetic
Operation	rC ← (signed) rA >> ((unsigned) $rB_{4..0}$)
Assembler Syntax	`sra rC, rA, rB`
Example	`sra r6, r7, r8`
Description	Shifts rA right by the number of bits specified in $rB_{4..0}$ (duplicating the sign bit), and then stores the result in rC. Bits 31–5 are ignored.
Usage	`sra` performs the signed >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A				B					C					0x3b
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0x3b				0					0x3a					

srai

Instruction	shift right arithmetic immediate
Operation	rC ← (signed) rA >> ((unsigned) IMM5)
Assembler Syntax	`srai rC, rA, IMM5`
Example	`srai r6, r7, 3`
Description	Shifts rA right by the number of bits specified in IMM5 (duplicating the sign bit), and then stores the result in rC.

Usage	srai performs the signed >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	C = Register index of operand rC
	IMM5 = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x3a
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x3a					IMM5					0x3a					

srl

Instruction	shift right logical
Operation	rC ← (unsigned) rA >> ((unsigned) $rB_{4..0}$)
Assembler Syntax	srl rC, rA, rB
Example	srl r6, r7, r8
Description	Shifts rA right by the number of bits specified in $rB_{4..0}$ (inserting zeroes), and then stores the result in rC. Bits 31–5 are ignored.
Usage	srl performs the unsigned >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1b
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1b					0					0x3a					

srli

Instruction	shift right logical immediate
Operation	rC ← (unsigned) rA >> ((unsigned) IMM5)
Assembler Syntax	`srli rC, rA, IMM5`
Example	`srli r6, r7, 3`
Description	Shifts rA right by the number of bits specified in IMM5 (inserting zeroes), and then stores the result in rC.
Usage	`srli` performs the unsigned >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA
	`C` = Register index of operand rC
	`IMM5` = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1a
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1a					IMM5					0x3a					

stb / stbio l

Instruction	store byte to memory or I/O periphera
Operation	Mem8[rA + σ(IMM16)] ← rB$_{7..0}$

Assembler Syntax	`stb rB, byte_offset(rA)`
	
	`stbio rB, byte_offset(rA)`

Example	`stb r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores the low byte of rB to the memory byte specified by the effective address.
Usage	In processors with a data cache, this instruction may not generate an Avalon-MM bus cycle to noncache data memory immediately. Use the `stbio` instruction for peripheral I/O. In processors with a data cache, `stbio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `stbio` acts like `stb`.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (write) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Table 8-19: stb

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x25					

sth / sthio

Instruction	store halfword to memory or I/O peripheral
Operation	$Mem16[rA + \sigma(IMM16)] \leftarrow rB_{15..0}$

Assembler Syntax	`sth rB, byte_offset(rA)`
	
	 `sthio rB, byte_offset(rA)`

Example	`sth r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores the low halfword of rB to the memory location specified by the effective byte address. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may not generate an Avalon-MM data transfer immediately. Use the sthio instruction for peripheral I/O. In processors with a data cache, `sthio` bypasses the cache and is guaranteed to generate an Avalon-MM data transfer. In processors without a data cache, `sthio` acts like `sth`.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (write) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x2d					

stw / stwio

Instruction	store word to memory or I/O peripheral
Operation	Mem32[rA + σ(IMM16)] ← rB
Assembler Syntax	`stw rB, byte_offset(rA)` `stwio rB, byte_offset(rA)`
Example	`stw r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores rB to the memory location specified by the effective byte address. The effective byte address must be word aligned. If the byte address is not a multiple of 4, the operation is undefined.
Usage	In processors with a data cache, this instruction may not generate an Avalon-MM data transfer immediately. Use the `stwio` instruction for peripheral I/O. In processors with a data cache, `stwio` bypasses the cache and is guaranteed to generate an Avalon-MM bus cycle. In processors without a data cache, `stwio` acts like `stw`.

Exceptions	Supervisor-only data address
	Misaligned data address
	TLB permission violation (write)
	Fast TLB miss (data)
	Double TLB miss (data)
	MPU region violation (data)
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit signed immediate value

IMM16										0x35					

sub

Instruction	subtract
Operation	rC ← rA – rB
Assembler Syntax	sub rC, rA, rB
Example	sub r6, r7, r8
Description	Subtract rB from rA and store the result in rC.

Usage	Carry Detection (unsigned operands):
	The carry bit indicates an unsigned overflow. Before or after a sub operation, a carry out of the MSB can be detected by checking whether the first operand is less than the second operand. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. Both cases are shown in the following code:
	``` sub rC, rA, rB ```
	``` cmpltu rD, rA, rB ```
	``` sub rC, rA, rB ```
	``` bltu rA, rB, label ```
	``` # The original sub operation (optional) ```
	``` # rD is written with the carry bit ```
	``` # The original sub operation (optional) ```
	``` # Branch if carry generated ```
	Overflow Detection (signed operands):
	Detect overflow of signed subtraction by comparing the sign of the difference that is written to rC with the signs of the operands. If rA and rB have different signs, and the sign of rC is different than the sign of rA, an overflow occurred. The overflow condition can control a conditional branch, as shown in the following code:
	``` sub rC, rA, rB ```
	``` xor rD, rA, rB ```
	``` xor rE, rA, rC ```
	``` and rD, rD, rE ```
	``` blt rD, r0, label ```
	``` # The original sub operation ```
	``` # Compare signs of rA and rB ```
	``` # Compare signs of rA and rC ```
	``` # Combine comparisons ```
	``` # Branch if overflow occurred ```
Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x39
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x39					0					0x3a					

subi

Instruction	subtract immediate
Operation	rB ← rA – σ(IMMED)
Assembler Syntax	`subi rB, rA, IMMED`
Example	`subi r8, r8, 4`
Description	Sign-extends the immediate value IMMED to 32 bits, subtracts it from the value of rA and then stores the result in rB.
Usage	The maximum allowed value of IMMED is 32768. The minimum allowed value is –32767.
Pseudo-instruction	`subi` is implemented as `addi rB, rA, -IMMED`

sync

Instruction	memory synchronization
Operation	None
Assembler Syntax	`sync`
Example	`sync`

Description	Forces all pending memory accesses to complete before allowing execution of subsequent instructions. In processor cores that support in-order memory accesses only, this instruction performs no operation.
Exceptions	None
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0					0x36
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x36					0					0x3a					

trap

Instruction	trap
Operation	estatus ← status PIE ← 0 U ← 0 ea ← PC + 4 PC ← exception handler address
Assembler Syntax	trap trap imm5
Example	trap
Description	Saves the address of the next instruction in register `ea`, saves the contents of the `status` register in `estatus`, disables interrupts, and transfers execution to the exception handler. The address of the exception handler is specified with the Nios_II Processor parameter editor in Qsys. The 5-bit immediate field `imm5` is ignored by the processor, but it can be used by the debugger. `trap` with no argument is the same as `trap 0`.

Usage	To return from the exception handler, execute an `eret` instruction.
Exceptions	Trap
Instruction Type	R
Instruction Fields	`IMM5` = Type of breakpoint

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0x1d					0x2d
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x2d					IMM5					0x3a					

wrctl

Instruction	write to control register
Operation	ctlN ← rA
Assembler Syntax	`wrctl ctlN, rA`
Example	`wrctl ctl6, r3`
Description	Writes the value contained in register rA to the control register ctlN.
Exceptions	Supervisor-only instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA
	`N` = Control register index of operand ctlN

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					0					0x2e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x2e					N					0x3a					

wprs

Instruction	write to previous register set
Operation	prs.rC ← rA
Assembler Syntax	wprs rC, rA
Example	wprs r6, r7
Description	Copies the value of rA in the current register set to rC in the previous register set. This instruction can set r0 to 0 in a shadow register set.
Usage	The previous register set is specified by status.PRS. By default, status.PRS indicates the register set in use before an exception, such as an external interrupt, caused a register set change.
	To write to an arbitrary register set, software can insert the desired register set number in status.PRS prior to executing wprs.
	System software must use wprs to initialize r0 to 0 in each shadow register set before using that register set.
	If shadow register sets are not implemented on the Nios II core, wprs is an illegal instruction.
Exceptions	Supervisor-only instruction
	Illegal instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x14
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x14					0					0x3a					

xor

Instruction	bitwise logical exclusive or

Operation	rC ← rA ^ rB
Assembler Syntax	`xor rC, rA, rB`
Example	`xor r6, r7, r8`
Description	Calculates the bitwise logical exclusive-or of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1e					0					0x3a					

xorhi

Instruction	bitwise logical exclusive or immediate into high halfword
Operation	rB ← rA ^ (IMM16 : 0x0000)
Assembler Syntax	`xorhi rB, rA, IMM16`
Example	`xorhi r6, r7, 100`
Description	Calculates the bitwise logical exclusive XOR of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA
	B = Register index of operand rB
	IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x3c					

xori

Instruction	bitwise logical exclusive or immediate
Operation	rB ← rA ^ (0x0000 : IMM16)
Assembler Syntax	`xori rB, rA, IMM16`
Example	`xori r6, r7, 100`
Description	Calculates the bitwise logical exclusive OR of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x1c
